PEPTIDE INHIBITORS OF SELECTIN BINDING

Background of the Invention

This invention relates to peptides which inhibit binding of selectins such as P-selectin, E-selectin and L-selectin.

The adherence of platelets and leukocytes to vascular surfaces is a critical component of the inflammatory response and is part of a complex series of reactions involving the simultaneous and interrelated activation of the complement, coagulation, and immune systems.

The complement proteins collectively play a leading role in the immune system, both in the identification and in the removal of foreign substances and immune complexes, as reviewed by Muller-Eberhard, H.J., Ann. Rev. Biochem. 57: 321-347 (1988). Central to the complement system are the C3 and C4 proteins, which when activated covalently attach to nearby targets, marking them for clearance. In order to help control this process, a remarkable family of soluble and membrane-bound regulatory proteins has evolved, each of which interacts with activated C3 and/or C4 derivatives. The coagulation and inflammatory pathways are regulated in a coordinate fashion in response to tissue damage. For example, in addition to becoming adhesive for leukocytes, activated endothelial cells express tissue factor on the cell surface and decrease their surface expression of thrombomodulin, leading to a net facilitation of coagulation reactions on the cell surface. In some cases, a single

- 2 -

receptor can be involved in both inflammatory and coagulation processes.

Leukocyte adherence to vascular endothelium is a key initial step in migration of leukocytes to tissues in response to microbial invasion. Although a class of inducible leukocyte receptors, the CD11-CD18 molecules, are thought to have some role in adherence to endothelium, mechanisms of equal or even greater importance for leukocyte adherence appear to be due to inducible changes in the endothelium itself.

Activated platelets have also been shown to interact with both neutrophils and monocytes *in vitro*. The interaction of platelets with monocytes may be mediated in part by the binding of thrombospondin to platelets and monocytes, although other mechanisms have not been excluded. The mechanisms for the binding of neutrophils to activated platelets are not well understood, except that it is known that divalent cations are required. In response to vascular injury, platelets are known to adhere to subendothelial surfaces, become activated, and support coagulation. Platelets and other cells may also play an important role in the recruitment of leukocytes into the wound in order to contain microbial invasion.

Endothelium exposed to "rapid" activators such as thrombin and histamine becomes adhesive for neutrophils within two to ten minutes, while endothelium exposed to cytokines such as tumor necrosis factor and interleukin-1 becomes adhesive after one to six hours. The rapid endothelial-dependent leukocyte adhesion has been associated with expression of the lipid mediator platelet activating factor (PAF) on the cell surface, and presumably, the appearance of other endothelial surface receptors. The slower cytokine-inducible endothelial adhesion for leukocytes is mediated, at least in part, by E-selectin that is synthesized by endothelial cells after exposure to cytokines and then transported to the cell surface, where it binds neutrophils. The isolation, characterization and cloning of

- 3 -

E-selectin or ELAM-1 is reviewed by Bevilacqua, et al., in Science 243, 1160-1165 (1989). L-selectin, a peripheral lymph node homing receptor, also called "the murine Mel 14 antigen", "Leu 8", the "Leu 8 antigen" and "LAM-1", is
5 another structure on neutrophils, monocytes, and lymphocytes that binds lymphocytes to high endothelial venules in peripheral lymph nodes. The characterization and cloning of the protein is reviewed by Lasky, et al., Cell 56, 1045-1055 (1989) (mouse) and Tedder, et al., J. Exp. Med. 170, 123-133
10 (1989).

P-selectin, also known as GMP-140 (granule membrane protein 140), or PADGEM, is a cysteine-rich and heavily glycosylated integral membrane glycoprotein with an apparent molecular weight of 140,000 as assessed by sodium dodecyl
15 sulfate polyacrylamide gel electrophoresis (SDS-PAGE). P-selectin was first purified from human platelets by McEver and Martin, J. Biol. Chem. 259: 9799-9804 (1984). The protein is present in alpha granules of resting platelets but is rapidly redistributed to the plasma membrane following
20 platelet activation, as reported by Stenberg, et al., (1985). The presence of P-selectin in endothelial cells and its biosynthesis by these cells was reported by McEver, et al., Blood 70(5) Suppl. 1:355a, Abstract No. 1274 (1987). In endothelial cells, P-selectin is found in storage granules
25 known as the Weibel-Palade bodies. (McEver, et al. J. Clin. Invest. 84: 92-99 (1989) and Hattori, et al., J. Biol. Chem. 264: 7768-7771 (1989)). P-selectin (called GMP-140 or PADGEM) has also been reported to mediate the interaction of activated platelets with neutrophils and monocytes by Larsen,
30 et al., in Cell 59, 305-312 (October 1989) and Hamburger and McEver, Blood 75: 550-554 (1990).

The cDNA-derived amino acid sequence, reported by Johnston, et al., in Cell 56, 1033-1044 (March 24 1989), and in U.S. Serial No. 07/320,408 filed March 8, 1989, indicates
35 that it contains a number of modular domains that are likely to fold independently. Beginning at the N-terminus, these include a "lectin" domain, an "EGF" domain, nine tandem

consensus repeats similar to those in complement binding proteins, a transmembrane domain (except in a soluble form that appears to result from differential splicing), and a cytoplasmic tail.

5 When platelets or endothelial cells are activated by mediators such as thrombin, the membranes of the storage granules fuse with the plasma membrane, the soluble contents of the granules are released to the external environment, and membrane bound P-selectin is presented within seconds on the
10 cell surface. The rapid redistribution of P-selectin to the surface of platelets and endothelial cells as a result of activation suggested that this glycoprotein could play an important role at sites of inflammation or vascular disruption.

15 This important role has been confirmed by the observation that P-selectin is a receptor for neutrophils (Geng et al., Nature 343:757-760 (1990); Hamburger and McEver, Blood 75:550-554 (1990)), monocytes (Larsen, et al. Cell 59:305-312 (1989)); Moore, et al., J. Cell Biol.
20 112:491-499 (1991)), and perhaps a subset of lymphocytes (Moore, et al. J. Cell Biol. 112:491-499 (1991)). Thus, GMP-140 can serve as a receptor for leukocytes following its rapid mobilization to the surfaces of platelets and endothelial cells stimulated with agonists such as thrombin.
25 This role in leukocyte recruitment may be important in hemostatic and inflammatory processes in both physiologic and pathologic states.

 Peptides derived from P-selectin are described in U.S. Serial No. 07/554,199 entitled "Functionally Active
30 Selectin-Derived Peptides" filed July 17, 1990 by Rodger P. McEver that are useful in diagnostics and in modulating the hemostatic and inflammatory responses in a patient wherein a therapeutically effective amount of a peptide capable of blocking leukocyte recognition of P-selectin is administered
35 to the patient. U.S. Serial No. 07/554,199 filed July 17, 1990, also discloses that peptide sequences within the lectin domain of P-selectin, having homology with the lectin domains

of other proteins, especially E-selectin and the L-selectin, selectively inhibit neutrophil adhesion to purified P-selectin, and can therefore be used in diagnostic assays of patients and diseases characterized by altered binding by these molecules, in screening assays for compounds altering this binding, and in clinical applications to inhibit or modulate interactions of leukocytes with platelets or endothelial cells involving coagulation and/or inflammatory processes.

10 E-selectin, L-selectin, and P-selectin have been termed "selectins", based on their related structure and function. E-selectin is not present in unstimulated endothelium. However, when endothelium is exposed to cytokines such as tumor necrosis factor or interleukin-1, the
15 gene for E-selectin is transcribed, producing RNA which in turn is translated into protein. The result is that E-selectin is expressed on the surface of endothelial cells one to four hours after exposure to cytokines, as reported by Bevilacqua et al., Proc.Natl.Acad.Sci.USA 84: 9238-9242
20 (1987) (in contrast to P-selectin, which is stored in granules and presented on the cell surface within seconds after activation). E-selectin has been shown to mediate the adherence of neutrophils to cytokine-treated endothelium and thus appears to be important in allowing leukocytes to
25 migrate across cytokine-stimulated endothelium into tissues. The cDNA-derived primary structure of E-selectin indicates that it contains a "lectin" domain, an EGF domain, and six (instead of the nine in P-selectin) repeats similar to those of complement-regulatory proteins, a transmembrane domain,
30 and a short cytoplasmic tail. There is extensive sequence homology between P-selectin and E-selectin throughout both proteins, but the similarity is particularly striking in the lectin and EGF domains.

 Homing receptors are lymphocyte surface structures
35 that allow lymphocytes to bind to specialized endothelial cells in lymphatic tissues, termed high endothelial cells or high endothelial venules (reviewed by Yednock and Rosen,

- 6 -

Advances in Immunology, vol. 44, F.I. Dixon, ed., 313-378 (Academic Press, New York 1989). This binding allows lymphocytes to migrate across the endothelium into the lymphatic tissues where they are exposed to processed
5 antigens. The lymphocytes then re-enter the blood through the lymphatic system. L-selectin, a lymphocyte homing receptor, contains a lectin domain, an EGF domain, two complement-binding repeats, a transmembrane domain, and a short cytoplasmic tail. L-selectin also shares extensive
10 sequence homology with P-selectin, particularly in the lectin and EGF domains.

Based on a comparison of the lectin domains between P-selectin, E-selectin, and L-selectin, it may be possible to select those peptides inhibiting binding of neutrophils to P-
15 selectin which will inhibit binding of E-selectin, L-selectin, and other homologous selectins, to components of the inflammatory process, or, conversely, which will inhibit only P-selectin binding.

The *in vivo* significance of platelet-leukocyte
20 interactions has not been studied carefully. However, in response to vascular injury, platelets are known to adhere to subendothelial surfaces, become activated, and support coagulation. Platelets and other cells may also play an important role in the recruitment of leukocytes into the
25 wound in order to contain microbial invasion. Conversely, leukocytes may recruit platelets into tissues at sites of inflammation, as reported by Issekutz, et al., Lab. Invest. 49:716 (1983).

The coagulation and inflammatory pathways are
30 regulated in a coordinate fashion in response to tissue damage. For example, in addition to becoming adhesive for leukocytes, activated endothelial cells express tissue factor on the cell surface and decrease their surface expression of thrombomodulin, leading to a net facilitation of coagulation
35 reactions on the cell surface. In some cases, a single receptor can be involved in both inflammatory and coagulation processes.

- 7 -

Proteins involved in the hemostatic and inflammatory pathways are of interest for diagnostic purposes and treatment of human disorders. However, there are many problems using proteins therapeutically. Proteins are usually expensive to produce in quantities sufficient for administration to a patient. Moreover, there can be a reaction against the protein after it has been administered more than once to the patient. It is therefore desirable to develop peptides having the same, or better, activity as the protein, which are inexpensive to synthesize, reproducible and relatively innocuous.

It is preferable to develop peptides which can be prepared synthetically, having activity at least equal to, or greater than, the peptides derived from the protein itself.

It is therefore an object of the present invention to provide peptides interacting with cells recognized by selectins, including P-selectin, E-selectin, and L-selectin.

It is another object of the present invention to provide methods for using these peptides to inhibit leukocyte adhesion to endothelium or to platelets.

It is a further object of the present invention to provide methods for using these peptides to modulate the immune response and the hemostatic pathway.

It is yet another object of the present invention to provide peptides for use in diagnostic assays relating to P-selectin, E-selectin and L-selectin.

Summary of the Invention

This invention relates to novel peptides having as their core region portions of the 109-118 amino acid sequence of P-selectin, E-selectin or L-selectin. More specifically, this invention relates to novel peptides of Formulas I and II:

(I)

(II)

or pharmaceutically acceptable salts thereof, wherein:

X' is an N-terminus amino acid linear sequence of from zero to 10 amino acids, and R¹ is a moiety attached to the terminal α amino group of X', or the terminal α -amino
5 group of the adjacent amino acid if X is zero;

X" is a C-terminus amino acid linear sequence of from zero to 10 amino acids, and R² is a moiety attached to the carboxyl carbon of X" or the carboxyl carbon of the adjacent amino acid if X" is zero;

10 A' is null (signifying no amino acid) or D- or L-cysteine;

A" is D- or L-cysteine;

B' is D- or L-histidine, D- or L-serine, D- or L-leucine, D- or L-phenylalanine, D- or L-asparagine, D- or L-
15 proline or D- or L-glutamine;

C' is D- or L-lysine, D- or L-histidine, D- or L-arginine, or D- or L-serine;

D' is D- or L-lysine, D- or L-leucine, D- or L-alanine, D- or L-phenylalanine, D- or L-histidine, D- or L-
20 arginine, or D- or L-serine;

E' is D- or L-lysine, D- or L-phenylalanine, D- or L-glutamine, or D- or L-arginine;

F' is D- or L-histidine, D- or L-leucine, D- or L-alanine, D- or L-isoleucine, D- or L-threonine, or D- or L-
25 arginine;

G' is D- or L-alanine, D- or L-phenylalanine, D- or L-histidine, D- or L-isoleucine, or D- or L-glutamine;

H' is D- or L-leucine, D- or L-phenylalanine, D- or L-isoleucine, D- or L-proline, or D- or L-alanine;

30 I' is D- or L-cysteine, D- or L-phenylalanine, D- or L-isoleucine, D- or L-histidine, D- or L-leucine, D- or L-valine, D- or L-threonine, or D- or L-serine;

I" is D- or L-cysteine;

J' is D- or L-tyrosine, D- or L-phenylalanine, D-
35 or L-isoleucine, or D- or L-valine;

R^1 is hydrogen (signifying a free N-terminal group), lower alkyl, aryl, formyl, alkanoyl, aroyl, alkyloxycarbonyl or aryloxycarbonyl;

R^2 is OH (signifying a free C-terminal carboxylic acid), OR^3 , signifying ester, where R^3 is lower alkyl or aryl or R^2 is NR^5R^6 where R^5 and R^6 are each selected independently from hydrogen, lower alkyl, aryl or cyclic alkyl.

The peptides of Formulas I and II have as their core region the 109-118 amino acid sequence of the selectins. Residue 1 is defined as the N-terminus of the mature protein after the cleavage of the signal peptide.

The peptides of Formulas I and II should inhibit the binding of neutrophils to P-selectin in concentrations of peptide ranging from about 10 to about 1500 μM . Tests also indicate that alterations within the core sequence, as well as N-terminal and C-terminal flanking regions, do not result in loss of biological activity.

This invention relates not only to the novel peptides of Formulas I and II, but also to pharmaceutical compositions comprising them, to diagnostic and therapeutic methods utilizing them, and to methods of preparing them.

Detailed Description of the Invention

Preferred peptides of this invention are those of Formula I and II wherein, together or independently: R^1 is hydrogen or acetyl (Ac) and R^2 is OH or NH_2 . More preferred are those peptides wherein R^2 is NH_2 .

One group of preferred peptides includes those of Formula I where, independently, A' is null, B' is Phe, His, Leu, Asn or Ser; C' is Lys or Arg; D' is Lys, Phe, Leu, Ala; E' is Lys or Arg; F' is Leu or Arg; G' is Ala; H' is Leu; I' is Cys, Ile or Phe, and J' is Tyr.

Test results have indicated that peptides in which E' is Arg have superior activity. Accordingly, a more preferred group of peptides are those in which E' is Arg.

Specifically preferred peptides include the following:

	(SEQ ID NO:69)	Ser-Arg-Arg-Lys-Leu-Ala-Leu-Cys-Tyr-NH ₂ ;
	(SEQ ID NO:70)	Ser-Ser-Lys-Lys-Leu-Ala-Leu-Cys-Tyr-NH ₂ ;

30 More preferred peptides are those with Sequence ID Nos. 2, 6, 8, 9, 12, 15, 20, 31, 33, 35, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 61, 62, 63, 64, 65, 66, 68, and 69.

As used herein, the term "alkyl" includes branched, straight-chain, and cyclic saturated hydrocarbons. The term "lower alkyl" means an alkyl having from one to six carbon atoms, such as methyl, ethyl, propyl, isopropyl, butyl, isobutyl, t-butyl, pentyl, isopentyl, neopentyl, cyclopentylmethyl and hexyl. The term "alkanoyl" means

wherein R^7 is a alkyl group.

The term "aroyl" means

wherein R^8 is an aryl group. The term "aryl" means an aromatic or heteroaromatic structure having between one and three rings, which may or may not be ring fused structures, and are optionally substituted with halogens, carbons, or other heteroatoms such as nitrogen (N), sulfur (S), phosphorus (P), and boron (B).

The term alkoxycarbonyl means

wherein R^9 is a lower alkyl group.

The term aryloxycarbonyl means

wherein R^{10} is an aryl and arylmethyl group.

Halogen refers to fluorine, chlorine, bromine or iodine.

The term "terminal α -amino group of X" refers to the α -amino group of the N-terminal amino acid of X.

The peptides of Formulas I and II can be used in the form of the free peptide or a pharmaceutically acceptable salt. Amine salts can be prepared by treating the peptide with an acid according to known methods. Suitable acids include inorganic acids such as hydrochloric acid, hydrobromic acid, perchloric acid, nitric acid, thiocyanic acid, sulfuric acid, and phosphoric acid, and organic acids

- 14 -

such as formic acid, acetic acid, propionic acid, glycolic acid, lactic acid, pyruvic acid, oxalic acid, malonic acid, succinic acid, maleic acid, fumaric acid, anthranilic acid, cinnamic acid, naphthalenesulfonic acid, and sulfanilic acid.

5 Carboxylic acid groups in the peptide can be converted to a salt by treating the peptide with a base according to known methods. Suitable bases include inorganic bases such as sodium hydroxide, ammonium hydroxide, and potassium hydroxide, and organic bases such as mono-, di-,
10 and tri-alkyl and aryl amines (e.g., triethylamine, diisopropylamine, methylamine, and dimethylamine and optionally substituted mono-, di, and tri-ethanolamines.

As referred to herein, the amino acid components of the peptides and certain materials used in their preparation
15 are identified by abbreviations for convenience. These abbreviations are as follows:

- 15 -

	Amino Acid	Abbreviations	
	L-alanine	Ala	A
	D-alanine	D-Ala	a
	L-arginine	Arg	R
5	D-arginine	D-Arg	r
	D-asparagine	D-Asn	n
	L-asparagine	Asn	N
	L-aspartic acid	Asp	D
	D-aspartic acid	D-Asp	d
10	L-cysteine	Cys	C
	D-cysteine	D-Cys	c
	L-glutamic acid	Glu	E
	D-glutamic acid	D-Glu	e
	L-glutamine	Gln	Q
15	D-glutamine	D-Gln	q
	glycine	Gly	G
	L-histidine	His	H
	D-histidine	D-His	h
	L-isoleucine	Ile	I
20	D-isoleucine	D-Ile	i
	L-leucine	Leu	L
	D-leucine	D-Leu	l
	L-lysine	Lys	K
	D-lysine	D-Lys	k
25	L-phenylalanine	Phe	F
	D-phenylalanine	D-Phe	f
	L-proline	Pro	P
	D-proline	D-Pro	p
	L-serine	Ser	S
30	D-serine	D-Ser	s
	L-threonine	Thr	T
	D-threonine	D-Thr	t
	L-tyrosine	Tyr	Y
	D-tyrosine	D-Tyr	y
35	L-tryptophan	Trp	W
	D-tryptophan	D-Trp	w
	L-valine	Val	V
	D-valine	D-Val	v
	L-methionine	Met	M
40	D-methionine	D-Met	m

	Reagents	Abbreviations
	Trifluoroacetic acid	TFA
	Methylene chloride	CH ₂ Cl ₂
	N,N-Diisopropylethylamine	DIEA
45	N-Methylpyrrolidone	NMP
	1-Hydroxybenzotriazole	HOBT
	Dimethylsulfoxide	DMSO
	Acetic anhydride	Ac ₂ O
	Diisopropylcarbodiimide	DIC
50	Acetic acid	HOAc

Amino acids preceded by L- or D- refer, respectively, to the L- or D- enantiomer of the amino acid, whereas amino acids not preceded by L- or D- refer to the L-enantiomer.

Methods of Preparation of Peptides

- 5 The peptides can generally be prepared following known techniques, as described, for example, in the cited publications, the teachings of which are specifically incorporated herein. In a preferred method, the peptides are prepared following the solid-phase synthetic technique
- 10 initially described by Merrifield in J.Amer.Chem.Soc., 85, 2149-2154 (1963). Other techniques may be found, for example, in M. Bodanszky, et al, Peptide Synthesis, second edition, (John Wiley & Sons, 1976), as well as in other reference works known to those skilled in the art.
- 15 Appropriate protective groups usable in such syntheses and their abbreviations will be found in the above text, as well as in J.F.W. McOmie, Protective Groups in Organic Chemistry, (Plenum Press, New York, 1973). The common protective groups used herein are t-butyloxycarbonyl (Boc),
- 20 fluorenylmethoxycarbonyl (Fmoc), benzyl (Bzl), tosyl (Tos), o-bromo-phenylmethoxycarbonyl (BrCBZ), phenylmethoxycarbonyl (CBZ), 2-chloro-phenylmethoxycarbonyl (2-Cl-CBZ), 4-methoxy-2,3,6-trimethylbenzenesulfonyl (Mtr), trityl (Trt), formyl (CHO), and tertiary butyl (t-Bu).
- 25 General synthetic procedures for the synthesis of peptides of Formula I and II the invention by solid phase methodology are as follows:

- 17 -

A. General Synthetic Procedures For Solid Phase Peptide Synthesis Using N^α-Boc Protection

		<u>REPETITIONS</u>	<u>TIME</u>
	1. 25% TFA in CH ₂ Cl ₂	1	3 min.
5	2. 50% TFA in CH ₂ Cl ₂	1	16 min.
	3. CH ₂ Cl ₂	5	3 min.
	4. 5% DIEA in NMP	2	4 min.
	5. NMP	6	5 min.
	6. Coupling step	1	57 min.
10	a. Preformed BOC-Amino Acid-HOBT active ester in NMP		37 min.
	b. DMSO		16 min.
	c. DIEA		5 min.
	7. 10% Ac ₂ O, 5% DIEA in NMP	1	9 min.
15	8. CH ₂ Cl ₂	5	3 min.

B. General Synthetic Procedure For Solid Phase Peptide Synthesis Using N^α-Fmoc Protection

		<u>REPETITIONS</u>	<u>TIME</u>
	1. 50% piperidine in DMF	1	1 min.
20	2. 50% piperidine in NMP	1	12 min.
	3. NMP	7	1 min.
	4. Coupling	1	71 min.
	Amino acid and HOBT in NMP added to the resin followed by the addition of DIC in NMP.		
25	HOBT active ester in NMP or		
	5. NMP	1	1 min.
	6. Repeat steps 4-5	1	
	7. NMP	2	1 min.

N-terminal acetylation on the deprotected N^α-amino group of peptides synthesized using either Boc or Fmoc strategies can be accomplished with 10% Ac₂O and 5% DIEA in NMP, followed by washing of the peptide resin with NMP and/or CH₂Cl₂.

The peptides can also be prepared using standard genetic engineering techniques known to those skilled in the art. For example, the peptide can be produced enzymatically

by inserting nucleic acid encoding the peptide into an expression vector, expressing the DNA, and translating the DNA into the peptide in the presence of the required amino acids. The peptide is then purified using chromatographic or electrophoretic techniques, or by means of a carrier protein which can be fused to, and subsequently cleaved from, the peptide by inserting into the expression vector in phase with the peptide encoding sequence a nucleic acid sequence encoding the carrier protein. The fusion protein-peptide may be isolated using chromatographic, electrophoretic or immunological techniques (such as binding to a resin via an antibody to the carrier protein). The peptide can be cleaved using chemical methodology or enzymatically, as by, for example, hydrolases.

Peptides of the invention can also be prepared using solution methods, by either stepwise or fragment condensations. An appropriately alpha amino-protected amino acid is coupled to an appropriately alpha carboxyl protected amino acid (such protection may not be required depending on the coupling method chosen) using diimides, symmetrical or unsymmetrical anhydrides, BOP, or other coupling reagents or techniques known to those skilled in the art. These techniques may be either or enzymatic. The alpha amino and/or alpha carboxyl protecting groups are removed and the next suitably protected amino acid or block of amino acids are coupled to extend the growing peptide. Various combinations of protecting groups and of chemical and/or enzymatic techniques and assembly strategies can be used in each synthesis.

The peptides of Formula II are cyclic by virtue of the formation of a disulfide bond between cysteine residues. The general techniques for the formation of this bond are described by G. Barany and R. B. Merrifield in The Peptides Analysis, Synthesis, Biology, (Academic Press, Inc., 1979), as well as in other reference works known to those skilled in the art.

Methods of Preparation of Pharmaceutical Compositions

Pharmaceutical compositions of this invention comprise a pharmaceutically acceptable carrier or diluent and an effective quantity of one or more of the peptides of Formula I or II or an acid or base salt thereof. The carrier or diluent may take a wide variety of forms depending on the form of preparation desired for administration, e.g., sublingual, rectal, nasal, oral, or parenteral.

In preparing the compositions in oral dosage form, any of the usual pharmaceutical media may be employed, for example, waters, oils, alcohols, flavoring agents, preservatives, and coloring agents, to make an oral liquid preparation (e.g., suspension, elixir, or solution) or with carriers such as starches, sugars, diluents, granulating agents, lubricants, binders, and disintegrating agents, to make an oral solid preparation (e.g., powder, capsule, or tablet).

Controlled release forms or enhancers to increase bioavailability may also be used. Because of their ease in administration, tablets and capsules represent the most advantageous oral dosage unit form, in which case solid pharmaceutical carriers are employed. If desired, tablets may be sugar coated or enteric coated by standard techniques.

For parenteral products, the carrier will usually be sterile water, although other ingredients to aid solubility or as preservatives may be included. Injectable suspensions may also be prepared, in which case appropriate liquid carriers and suspending agents can be employed.

The peptides can also be administered locally at a wound or inflammatory site by topical application of a solution or cream.

Alternatively, the peptide may be administered in liposomes or microspheres (or microparticles). Methods for preparing liposomes and microspheres for administration to a patient are known to those skilled in the art. U.S. Patent No. 4,789,734 describes methods for encapsulating biological materials in liposomes. Essentially, the material is

- 20 -

dissolved in an aqueous solution, the appropriate phospholipids and lipids added, along with surfactants if required, and the material dialyzed or sonicated, as necessary. A review of known methods is by G. Gregoriadis, Chapter 14, "Liposomes", Drug Carriers in Biology and Medicine, pp. 287-341 (Academic Press, 1979). Microspheres formed of polymers or proteins are well known to those skilled in the art, and can be tailored for passage through the gastrointestinal tract directly into the bloodstream.

Alternatively, the peptide can be incorporated and the microspheres, or composite of microspheres, implanted for slow release over a period of time, ranging from days to months. See, for example, U.S. Patents Nos. 4,906,474, 4,925,673 and 3,625,214.

The peptides are generally active when administered parenterally in amounts of at least about 1 $\mu\text{g/kg}$ body weight. Effective doses by other routes of administration are generally those which result in similar blood level to i.v. doses of at least about 1 $\mu\text{g/Kg}$. For treatment to prevent organ injury in cases involving reperfusion, the peptides may be administered parenterally in amounts from about 0.01 to about 10 mg/kg body weight. Generally, the same range of dosage amounts may be used in treatment of other diseases or of conditions where inflammation is to be reduced. This dosage will be dependent, in part, on whether one or more peptides are administered. A synergistic effect may be seen with combinations of peptides from different, or overlapping, regions of the lectin domain, or in combination with peptides derived from the EGF domain of P-, E- or L-selectin. For treatment to prevent organ injury in cases involving reperfusion, the peptides may be administered parenterally in amounts from about 0.01 to about 10 mg/kg body weight. Generally, the same range of dosage amounts may be used in treatment of other diseases or of conditions where inflammation is to be reduced. This dosage will be dependent, in part, on whether one or more peptides are administered. A synergistic effect may be seen with

- 21 -

combinations of peptides from different, or overlapping, regions of the lectin domain, or in combination with peptides derived from the EGF domain of P-selectin.

Methods for Demonstrating Binding

5 Peptides that are biologically active are those which inhibit binding of neutrophils, monocytes, subsets of lymphocytes or other cells to P-selectin, or which inhibit leukocyte adhesion to endothelium that is mediated by ELAM-1 and/or the homing receptor.

10 Peptides can be screened for their ability to inhibit adhesion to cells, for example, neutrophil adhesion to purified P-selectin immobilized on plastic wells, using the assay described by Geng, et al., Nature 343, 757-760 (1990).

 Human neutrophils are isolated from heparinized whole
15 blood by density gradient centrifugation on Mono-Poly resolving media, Flow Laboratories. Neutrophil suspensions are greater than 98% pure and greater than 95% viable by trypan blue exclusion. For adhesion assays, neutrophils are suspended at a concentration of 2×10^6 cells/mL in Hanks' balanced salt solution containing 1.26 mM Ca^{2+} and 0.81 mM Mg^{2+} (HBSS, Gibco) with g mg/mL human serum albumin (HBSS/HSA). Adhesion assays are conducted in triplicate in
20 96-well microtiter plates, Corning, incubated at 4°C overnight with 50 microliters of various protein solutions.

25 P-selectin is isolated from human platelet lysates by immunoaffinity chromatography on antibody S12-Sepharose™ and ion-exchange chromatography on a Mono-Q™ column (FLPC, Pharmacia Fine Chemicals), as follows.

 Outdated human platelet packs (100 units) obtained
30 from a blood bank and stored at 4°C are pooled, adjusted to 5mM EDTA at pH 7.5, centrifuged at 4,000 rpm for 30 minutes in 1 liter bottles, then washed three times with 1 liter of 0.1 M NaCl, 20 mM Tris pH 7.5 (TBS), 5 mM EDTA, 5 mM benzamidine.

35 The pellets are then resuspended in a minimum amount of wash buffer and made 1mM in DIFP, then frozen in 50 mL

- 22 -

screwtop tubes at -80°C. The frozen platelets are thawed and resuspended in 50 mL TBS, 5 mM benzamidine, 5 mM EDTA pH 7.5, 100 M leupeptin. The suspension is frozen and thawed two times in a dry ice-acetone bath using a 600 mL lyophilizing flask, then homogenized in a glass/teflon mortar and pestle and made 1 mM in DIFP. The NaCl concentration is adjusted to 0.5 M with a stock solution of 4 M NaCl. After stirring the suspension at 4°C, it is centrifuged in polycarbonate tubes at 33,000 rpm for 60 minutes at 4°C. The supernatant (0.5 M NaCl wash) is removed and saved; this supernatant contains the soluble form of P-selectin. Care is taken not to remove the top part of the pellet with the supernatant. The pellets are then homogenized in extraction buffer (TBS, 5 mM benzamidine, 5 mM EDTA, pH 7.5, 100 µM leupeptin, 2% Triton X-100). After centrifugation at 19,500 rpm for 25 minutes at 4°C, the supernatant is removed. The extraction procedure is repeated with the pellet and the supernatant is combined with the first supernatant. The combined extracts, which contain the membrane form of P-selectin, are adjusted to 0.5 M NaCl.

The soluble fraction (0.5 M NaCl wash) and the membrane extract (also adjusted to 0.5 M NaCl) are absorbed with separate pools of the monoclonal antibody S12 (directed to P-selectin) previously coupled to Affigel (Biorad) at 5 mg/mL for 2 hours at 4°C. After letting the resins settle, the supernatants are removed. The S12 Affigel containing bound GMP-140 is then loaded into a column and washed overnight at 4°C with 400 mL of 0.5 M NaCl, 20 mM Tris pH 7.5, 0.01% Lubrol PX.

Bound P-selectin is eluted from the S12 Affigel with 100 mL of 80% ethylene glycol, 1 mM MES pH 6.0, 0.01% Lubrol PX. Peak fractions with absorbance at 280 nm are pooled. Eluates are dialyzed against TBS with 0.05% Lubrol, then applied to a Mono Q column (FPLC from Pharmacia). The concentrated protein is step eluted with 2 M NaCl, 20 mM Tris pH 7.5 (plus 0.05% Lubrol PX for the membrane fraction). Peak fractions are dialyzed into TBS pH 7.5 (plus 0.05% Lubrol PX for the membrane fraction).

- 23 -

P-selectin is plated at 5 micrograms/mL and the control proteins: human serum albumin (Alb), platelet glycoprotein IIb/IIIa (IIb), von Willebrand factor (vWF), fibrinogen (FIB), thrombomodulin (TM), gelatin (GEL) or human serum (HS), are added at 50 micrograms/mL. All wells are blocked for 2 hours at 22°C with 300 microliters HBSS containing 10 mg/mL HSA, then washed three times with HBSS containing 0.1% Tween-20 and once with HBSS. Cells (2×10^5 per well) are added to the wells and incubated at 22°C for 20 minutes. The wells are then filled with HBSS/HSA, sealed with acetate tape (Dynatech), and centrifuged inverted at 150 g for 5 minutes. After discarding nonadherent cells and supernates, the contents of each well are solubilized with 200 microliters 0.5% hexadecyltrimethylammonium bromide, Sigma, in 50 mM potassium phosphate, pH. 6.0, and assayed for myeloperoxidase activity, Ley, et al., Blood 73, 1324-1330 (1989). The number of cells bound is derived from a standard curve of myeloperoxidase activity versus numbers of cells. Under all assay conditions, the cells release less than 5% of total myeloperoxidase and lactate dehydrogenase. Inhibition is read as a lower percent adhesion, so that a value of 5% means that 95% of the specific adhesion was inhibited.

Peptides are tested at concentrations between 1.0 mM to 0.001 mM and a percent inhibition calculated for each concentration. A least squares fit is done on a plot of peptide concentration versus percent inhibition and an IC_{50} value calculated. The IC_{50} is defined as the concentration of peptide that will inhibit 50% of the neutrophil binding to the P-selectin lawn.

Activity data are presented either as an IC_{50} for each peptide or the percent inhibition at a defined concentration.

Table I gives the IC_{50} values in mM for peptides of the invention in inhibiting the binding of human neutrophils to P-selectin.

Clinical Applications

Since the selectins have several functions related to
5 leukocyte adherence, inflammation, and coagulation, compounds
which interfere with binding of P-selectin, E-selectin or L-
selectin can be used to modulate these responses.

For example, the peptides can be used to competitively
inhibit leukocyte adherence by competitively binding to P-
10 selectin receptors on the surface of leukocytes. This kind
of therapy would be particularly useful in acute situations
where effective, but transient, inhibition of leukocyte-
mediated inflammation is desirable. Chronic therapy by
infusion of the peptides may also be feasible in some
15 circumstances.

An inflammatory response may cause damage to the host
if unchecked, because leukocytes release many toxic molecules
that can damage normal tissues. These molecules include
proteolytic enzymes and free radicals. Examples of
20 pathological situations in which leukocytes can cause tissue
damage include injury from ischemia and reperfusion,
bacterial sepsis and disseminated intravascular coagulation,
adult respiratory distress syndrome, tumor metastasis,
rheumatoid arthritis and atherosclerosis.

25 Reperfusion injury is a major problem in clinical
cardiology. Therapeutic agents that reduce leukocyte
adherence in ischemic myocardium can significantly enhance
the therapeutic efficacy of thrombolytic agents.
Thrombolytic therapy with agents such as tissue plasminogen
30 activator or streptokinase can relieve coronary artery
obstruction in many patients with severe myocardial ischemia
prior to irreversible myocardial cell death. However, many
such patients still suffer myocardial neurosis despite
restoration of blood flow. This "reperfusion injury" is
35 known to be associated with adherence of leukocytes to
vascular endothelium in the ischemic zone, presumably in part

- 27 -

because of activation of platelets and endothelium by thrombin and cytokines that makes them adhesive for leukocytes (Romson et al., Circulation 67: 1016-1023 (1983)). These adherent leukocytes can migrate through the endothelium and destroy ischemic myocardium just as it is being rescued by restoration of blood flow.

There are a number of other common clinical disorders in which ischemia and reperfusion results in organ injury mediated by adherence of leukocytes to vascular surfaces, including strokes; mesenteric and peripheral vascular disease; organ transplantation; and circulatory shock (in this case many organs might be damaged following restoration of blood flow).

Bacterial sepsis and disseminated intravascular coagulation often exist concurrently in critically ill patients. They are associated with generation of thrombin, cytokines, and other inflammatory mediators, activation of platelets and endothelium, and adherence of leukocytes and aggregation of platelets throughout the vascular system. Leukocyte-dependent organ damage is an important feature of these conditions.

Adult respiratory distress syndrome is a devastating pulmonary disorder occurring in patients with sepsis or following trauma, which is associated with widespread adherence and aggregation of leukocytes in the pulmonary circulation. This leads to extravasation of large amounts of plasma into the lungs and destruction of lung tissue, both mediated in large part by leukocyte products.

Two related pulmonary disorders that are often fatal are in immunosuppressed patients undergoing allogeneic bone marrow transplantation and in cancer patients suffering from complications that arise from generalized vascular leakage resulting from treatment with interleukin-2 treated LAK cells (lymphokine-activated lymphocytes). LAK cells are known to adhere to vascular walls and release products that are presumably toxic to endothelium. Although the mechanism by which LAK cells adhere to endothelium is now known, such

cells could potentially release molecules that activate endothelium and then bind to endothelium by mechanisms similar to those operative in neutrophils.

Tumor cells from many malignancies (including
5 carcinomas, lymphomas, and sarcomas) can metastasize to distant sites through the vasculature. The mechanisms for adhesion of tumor cells to endothelium and their subsequent migration are not well understood, but may be similar to those of leukocytes in at least some cases. The association
10 of platelets with metastasizing tumor cells has been well described, suggesting a role for platelets in the spread of some cancers. Recently, it was reported that P-selectin binds to tumor cells in a variety of human carcinoma tissue sections (colon, lung, and breast), and that P-selectin binds
15 to the cell surface of a number of cell lines derived from various carcinomas, but not from melanomas. Aruffo, A., et al., Proc. Natl. Acad. Sci. USA, 89, 2292-2296 (1992). Aruggo et al. also reference earlier work suggesting that E-selectin might be involved in tumor metastasis by mediating
20 the adhesion of a colon carcinoma cell line (HT-20) to activated endothelial cells *in vitro*. Platelet-leukocyte interactions are believed to be important in atherosclerosis. Platelets might have a role in recruitment of monocytes into atherosclerotic plaques; the accumulation of monocytes is
25 known to be one of the earliest detectable events during atherogenesis. Rupture of a fully developed plaque may not only lead to platelet deposition and activation and the promotion of thrombus formation, but also the early recruitment of neutrophils to an area of ischemia.

30 Another area of potential application is in the treatment of rheumatoid arthritis.

The criteria for assessing response to therapeutic modalities employing these peptides, and, hence, effective dosages of the peptides of this invention for treatment, are
35 dictated by the specific condition and will generally follow standard medical practices. For example, the criteria for the effective dosage to prevent extension of myocardial

- 29 -

infarction would be determined by one skilled in the art by looking at marker enzymes of myocardial necrosis in the plasma, by monitoring the electrocardiogram, vital signs, and clinical response. For treatment of acute respiratory distress syndrome, one would examine improvements in arterial oxygen, resolution of pulmonary infiltrates, and clinical improvement as measured by lessened dyspnea and tachypnea. For treatment of patients in shock (low blood pressure), the effective dosage would be based on the clinical response and specific measurements of function of vital organs such as the liver and kidney following restoration of blood pressure. Neurologic function would be monitored in patients with stroke. Specific tests are used to monitor the functioning of transplanted organs; for example, serum creatinine, urine flow, and serum electrolytes in patients undergoing kidney transplantation.

Diagnostic Reagents

The peptides can also be used for the detection of human disorders in which the ligands for the selectins might be defective. Such disorders would most likely be seen in patients with increased susceptibility to infections in which leukocytes might not be able to bind to activated platelets or endothelium. Cells to be tested, usually leukocytes, are collected by standard medically approved techniques and screened. Detection systems include ELISA procedures, binding of radiolabeled antibody to immobilized activated cells, flow cytometry, or other methods known to those skilled in the art. Inhibition of binding in the presence and absence of the lectin domain peptides can be used to detect defects or alterations in selectin binding. For selectins, such disorders would most likely be seen in patients with increased susceptibility to infections in which leukocytes would have defective binding to platelets and endothelium because of deficient leukocyte ligands for P-selectin.

- 30 -

The peptide is labeled radioactively, with a fluorescent tag, enzymatically, or with electron dense material such as gold for electron microscopy. The cells to be examined, usually leukocytes, are incubated with the
5 labeled peptides and binding assessed by methods described above with antibodies to P-selectin, or by other methods known to those skilled in the art. If ligands for P-, E- or L-selectin are also found in the plasma, they can also be measured with standard ELISA or radioimmunoassay procedures,
10 using labeled P-, E- or L-selectin-derived peptide instead of antibody as the detecting reagent.

The peptides can also be useful in *in vivo* imaging of concentrations of cells bearing selectin ligands. Cells expressing selectin ligands whose abnormally high local
15 concentrations or presence within the body such as cancer cells, is indicative of a disorder can be imaged using labeled peptides. These labels may be either intrinsic or extrinsic to the structure of the specific selectin peptide and may include, but not be limited to high energy emitters
20 such as ^{111}In or non-radioactive dense atoms to enhance x-ray contrast.

The following examples are presented to illustrate, not limit, the invention. In the examples and throughout the specification, parts are by weight unless otherwise
25 indicated.

EXAMPLE I: Cyclo-(cystinyl-leucyl-lysyl-lysyl-lysyl-histidyl-alanyl-leucyl-cystinyl)-tyrosine-amide

The peptide was prepared on an ABI Model 431A Peptide Synthesizer using Version 1.12 of the standard BOC software.
30 4-methyl benzhydrylamine resin (0.625 g, 0.5 mmol) was used in the synthesis. The final weight of the resin was 1.84 g.

The peptide was cleaved from the resin (1.8 g) using 18 mL of HF and 1.8 mL of anisole for 60 min at 0°C. The resin was washed with ether and the peptide extracted with
35 TFA/DCM (1:1, v/v) (3 x 15 mL) to give 720 mg of crude peptide. The crude linear peptide (500 mg) was dissolved in 80 mL of 50% HOAc and then added dropwise to the mixture of

- 31 -

water (1200 mL), NH_4OH (to keep pH approx. 7.5) and 0.01 M $\text{K}_3\text{Fe}(\text{CN})_6$ (approx. 3 mL). After each addition of the linear precursor to the reaction mixture (approx. 1.5 mL) the pH was adjusted to 7.5 by addition of NH_4OH followed by addition of
5 more $\text{K}_3\text{Fe}(\text{CN})_6$ solution. The total volume of the 0.01 M $\text{K}_3\text{Fe}(\text{CN})_6$ solution used for oxidation was 40 mL. An additional 2 mL of $\text{K}_3\text{Fe}(\text{CN})_6$ solution was added extra and the mixture was stirred over 20 min (pH = 7.5), then the pH was adjusted to 4-5 by addition of HOAc followed by stirring with
10 5 g of anion exchange AG 3-X4, 200-400 mesh, free base form (Bio-Rad) over 30 min. The resin was filtered off, washed with 5% acetic acid (3 x 100 mL) and combined fractions (approx. 1700 mL) were loaded onto a Vydac C-18 column (15 μ , 10 X 30 cm) eluting with 0-15% over 5 min and a 15-55%
15 gradient of 80% ethanol in 0.1% TFA over 55 min at a flow rate of 120 mL per min. Fractions were collected, analyzed by HPLC and pure fractions pooled, evaporated to approx. 100 mL and lyophilized to give 146 mg of white solids. Amino acid analysis: Ala 1.01 (1), Cys 1.60 (2), His 1.03 (1), Leu
20 2.00 (2), Lys 2.96 (3), Tyr 0.72 (1).

EXAMPLE II: Cyclo-(cystinyl-histidyl-lysyl-leucyl-lysyl-alanyl-alanyl-leucyl-cystinyl)-tyrosine-amide

The peptide was prepared on an ABI Model 431A Peptide
25 Synthesizer using Version 1.12 of the standard BOC software. 4-methyl benzhydrylamine resin (0.625 g, 0.5 mmol) was used in the synthesis. The final weight of the resin was 1.66 g.

The peptide was cleaved from the resin (1.6 g) using 16 mL of HF and 1.6 mL of anisole for 60 min at 0°C. The
30 resin was washed with ether and the peptide extracted with TFA/ CH_2Cl_2 (1:1, v/v) (3 x 15 mL) to give 748 mg of crude peptide. The crude linear peptide (500 mg) was dissolved in 65 mL of 70% HOAc and then added dropwise to the mixture of water (1200 mL), NH_4OH (to keep pH approx. 7.5) and 0.01 M
35 $\text{K}_3\text{Fe}(\text{CN})_6$ (approx. 3 mL). After each addition of the linear precursor to the reaction mixture (approx. 1.5 mL) the pH was adjusted to 7.5 by addition of NH_4OH followed by addition of

- 32 -

more $K_3Fe(CN)_6$ solution. The total volume of the 0.01 M $K_3Fe(CN)_6$ solution used for oxidation was 30 mL. An additional 2 mL of $K_3Fe(CN)_6$ solution was added extra and the mixture was stirred over 20 min (pH = 7.5), then the pH was
5 adjusted to 4-5 by addition of HOAc followed by stirring with 5 g of anion exchange AG 3-X4, 200-400 mesh, free base form (Bio-Rad) over 30 min. The resin was filtered off, washed with 5% acetic acid (3 x 100 mL) and combined fractions (approx. 1700 mL) were loaded onto a Vydac C-18 column (15 μ ,
10 10 x 30 cm) eluting with a 0-15% over 5 min and 15-55% gradient of 80% ethanol in 0.1% TFA over 55 min at a flow rate of 120 mL per min. Fractions were collected, analyzed by HPLC and pure fractions pooled and lyophilized to give 86 mg of white solid. Amino acid analysis: Ala 2.00 (2), Cys
15 1.55 (2), His 1.00 (1), Leu 2.01 (2), Lys 1.98 (2), Tyr 0.70 (1).

Ellman's test for quantitative determination of SH was negative.

20 **EXAMPLE III: Cystinyl-leucyl-lysyl-lysyl-lysyl-histidyl-alanyl-leucyl-cystinyl-tyrosine-amide**

The peptide was prepared on an ABI Model 431A Peptide Synthesizer using Version 1.12 of the standard BOC software. 4-methyl benzhydrylamine resin (0.625 g, 0.5 mmol) was used in the synthesis. The final weight of the resin was 1.84 g.

25 The peptide was cleaved from the resin (1.8 g) using 18 mL of HF and 1.8 mL of anisole for 60 min at 0°C. The resin was washed with ether and the peptide extracted with TFA/ CH_2Cl_2 (1:1, v/v) (3 x 15 mL) to give 720 mg of crude peptide.

30 The crude peptide (220 mg) was purified on a Vydac C-18 column (15 μ , 5 x 25 cm) eluting with a 15-45% gradient of 80% acetonitrile in 0.1% TFA over 120 min at a flow rate of 15 mL per min. Fractions were collected, analyzed by HPLC and pure fractions pooled and lyophilized to give 32 mg of
35 white solid. Amino acid analysis: Ala 1.02 (1), Cys 0.88 (2), His 1.06 (1), Leu 1.98 (2), Lys 2.94 (3), Tyr 0.87 (1).

- 33 -

EXAMPLE IV: Cystinyl-histidyl-lysyl-leucyl-lysyl-alanyl-alanyl-leucyl-cystinyl-tyrosine-amide

The peptide was prepared on an ABI Model 431A Peptide Synthesizer using Version 1.12 of the standard BOC software. 4-methyl benzhydrylamine resin (0.625 g, 0.5 mmol) was used in the synthesis. The final weight of the resin was 1.66 g.

The peptide was cleaved from the resin (1.6 g) using 16 mL of HF and 1.6 mL of anisole for 60 min at 0°C. The resin was washed with ether and the peptide extracted with TFA/CH₂Cl₂ (1:1 v/v) (3 x 15 mL) to give 748 mg of crude peptide.

The crude peptide (249 mg) was purified in two runs on a Vydac C-18 column (15μ, 5 x 25cm) eluting with a 5-45% gradient of 80% acetonitrile in 0.1% TFA over 120 min at a flow rate of 15 mL per min. Fractions were collected, analyzed by HPLC and pure fractions pooled and lyophilized to give 53 mg of white solid. Amino acid analysis: Ala 1.97 (2), Cys 0.91, (2), His 1.10 (1), Leu 1.98 (2), Lys 1.95 (2), Tyr 0.74 (1).

EXAMPLE V: Cyclo-(cystinyl-serinyl-lysyl-lysyl-lysyl-leucyl-alanyl-leucyl-cystinyl-tyrosine-amide)

The peptide was prepared on an ABI Model 431A Peptide Synthesizer using Version 1.12 of the standard BOC software. 4-methyl benzhydrylamine resin (0.625 g, 0.5 mmol) was used in the synthesis. The final weight of the resin was 1.61 g.

The peptide was cleaved from the resin (1.6 g) using 16 mL of HF and 1.6 mL of anisole for 60 min at 0°C. The resin was washed with ether and the peptide extracted with TFA/CH₂Cl₂ (1:1, v/v) (3 x 15 mL) to give 680 mg of crude peptide.

The crude linear peptide (460 mg) was dissolved in 60 mL of 50% HOAc and then added dropwise to the mixture of water (1200 mL), NH₄OH (to keep pH approximately 7.5) and 0.01 M K₃Fe(CN)₆ (approximately 3 mL). After each addition of the linear precursor to the reaction mixture (approximately 1.5 mL) its pH was adjusted to 7.5 by addition

- 34 -

of NH_4OH followed by addition of $\text{K}_3\text{Fe}(\text{CN})_6$ solution. The total volume of the 0.01 M $\text{K}_3\text{Fe}(\text{CN})_6$ solution used for oxidation was 37 mL. The additional 2 mL of $\text{K}_3\text{Fe}(\text{CN})_6$ solution was added extra and the mixture was stirred over 20 min (pH = 7.5), then the pH was adjusted to 4-5 by addition of HOAc followed by stirring with 5 g of anion exchange AG 3-X4, 200-400 mesh, free base form (Bio-Rad) over 30 min. The resin was filtered off, washed with 5% acetic acid (3 x 100 mL) and combined fractions (approximately 1650 mL) were loaded onto a Vydac C-18 column (15 μ , 10 x 30 cm) eluting with a 0-25% over 5 min and 25-55% gradient of 80% ethanol in 0.1% TFA over 55 min at a flow rate of 120 mL per min. Fractions were collected, analyzed by HPLC and pure fractions pooled, evaporated (approximately 100 mL) and lyophilized to give 158 mg of white solid. Amino acid analysis: Ala 1.02 (1), Cys 1.67 (2), Leu 1.99 (2), Lys 2.92 (3), Ser 0.77 (1), Tyr 0.78 (1).

EXAMPLE VI: Cystinyl-serinyl-lysyl-lysyl-lysyl-leucyl-alanyl-leucyl-cystinyl-tyrosine-amide

20

The peptide was prepared on an ABI Model 431A Peptide Synthesizer using Version 1.12 of the standard BOC software. 4-methyl benzhydrylamine resin (0.625 g, 0.5 mmol) was used in the synthesis. The final weight of the resin was 1.61 g.

25

The peptide was cleaved from the resin (1.6 g) using 16 mL of HF and 1.6 mL of anisole for 60 min at 0°C. The resin was washed with ether and the peptide extracted with TFA/ CH_2Cl_2 (1:1, v/v) (3 x 15 mL) to give 680 mg of crude peptide.

30

The crude peptide (220 mg) was purified on a Vydac C-18 column (15 μ , 10 x 30 cm) eluting with a 0-30% over 5 min and 30-60% gradient of 80% ethanol in 0.1% TFA over 50 min at a flow rate of 120 mL per min. Fractions were collected, analyzed by HPLC and semi-pure fractions pooled, evaporated (approximately 100 mL) and lyophilized to give 66 mg of semi-pure product.

35

- 35 -

The semi-pure peptide (66 mg) was repurified on a Vydac C-18 column (15 μ , 5 x 25 cm) eluting with a 20-50% gradient of 80% acetonitrile in 0.1% TFA over 120 min at a flow rate of 15 mL/min. Fractions were collected, analyzed 5 by HPLC and pure fractions pooled and lyophilized to give 25 mg of white solid.

Amino acid analysis: Ala 1.00 (1), Cys 1.71 (2), Leu 2.00 (2), Lys 3.00 (3), Ser 0.72 (1), Tyr 0.75 (1).

WHAT IS CLAIMED IS:

1. A peptide of Formula I or II:

(I)

(II)

or pharmaceutically acceptable salts thereof, wherein:

X' is an N-terminus amino acid linear sequence of from zero to 10 amino acids, and R¹ is a moiety attached to the terminal α amino group of X', or the terminal α-amino group of the adjacent amino acid if X is zero;

X'' is a C-terminus amino acid linear sequence of from zero to 10 amino acids, and R² is a moiety attached to the carboxyl carbon of X'' or the carboxyl carbon of the adjacent amino acid if X'' is zero;

A' is selected from the group consisting of null (signifying no amino acid) and D- or L-cysteine;

A'' is selected from the group consisting of D- and L-cysteine;

B' is selected from the group consisting of D- or L-histidine, D- or L-serine, D- or L-leucine, D- or L-phenylalanine, D- or L-asparagine, D- or L-proline, and D- or L-glutamine;

C' is selected from the group consisting of D- or L-lysine, D- or L-histidine, D- or L-arginine, and D- or L-serine;

D' is selected from the group consisting of D- or L-lysine, D- or L-leucine, D- or L-alanine, D- or L-phenylalanine, D- or L-histidine, D- or L-arginine, and D- or L-serine;

E' is selected from the group consisting of D- or L-lysine, D- or L-phenylalanine, D- or L-glutamine, and D- or L-arginine;

F' is selected from the group consisting of D- or L-histidine, D- or L-leucine, D- or L-alanine, D- or L-isoleucine, D- or L-threonine, and D- or L-arginine;

- 41 -

G' is selected from the group consisting of D- or L-alanine, D- or L-phenylalanine, D- or L-histidine, D- or L-isoleucine, and D- or L-glutamine;

5 H' is selected from the group consisting of D- or L-leucine, D- or L-phenylalanine, D- or L-isoleucine, D- or L-proline, and D- or L-alanine;

10 I' is selected from the group consisting of D- or L-cysteine, D- or L-phenylalanine, D- or L-isoleucine, D- or L-histidine, D- or L-leucine, D- or L-valine, D- or L-threonine, and D- or L-serine;

I" is selected from the group consisting of D- and L-cysteine;

15 J' is selected from the group consisting of D- or L-tyrosine, D- or L-phenylalanine, D- or L-isoleucine, and D- or L-valine;

R¹ is selected from the group consisting of hydrogen (signifying a free N-terminal group), lower alkyl, aryl, formyl, alkanoyl, aroyl, alkyloxycarbonyl or aryloxycarbonyl;

20 R² is selected from the group consisting of OH (signifying a free C-terminal carboxylic acid), OR³, signifying ester, where R³ is selected from the group consisting of lower alkyl and aryl; and NR⁵R⁶ where R⁵ and R⁶ are each selected independently from hydrogen, lower
25 alkyl, aryl or cyclic alkyl;

and pharmaceutically acceptable salts thereof.

2. The peptide of Claim 1 wherein R¹ is selected from the group consisting of hydrogen and acetyl.

30 3. The peptide of Claim 1 wherein R² is selected from the group consisting of OH and NH₂.

4. The peptide of Claim 3 wherein R² is NH₂.

5. A peptide of Claim 1 having Formula I.

- 42 -

6. A peptide of Claim 5 where R^1 is selected from the group consisting of hydrogen and acetyl and R^2 is selected from the group consisting of OH and NH_2 .

7. A peptide of Claim 6 wherein R^2 is NH_2 .

5 8. A peptide of Claim 5 wherein, independently, A' is null; B' is selected from the group consisting of Phe, His, Leu, Asn and Ser; C' is selected from the group consisting of Lys and Arg; D' is selected from the group consisting of Lys, Phe, Leu, and Ala; E' is selected from
10 the group consisting of Lys and Arg; F' is selected from the group consisting of Leu and Arg; G' is Ala; H' is Leu; I' is selected from the group consisting of Cys, Ile and Phe; and J' is Tyr.

9. A peptide of Claim 8 wherein R^2 is NH_2 .

15 10. A peptide of Claim 1 where E' is Arg.

11. A peptide of Claim 9 where E' is Arg.

12. A peptide of Claim 1 having Formula II.

13. A peptide of Claim 12 where R^1 is selected from the group consisting of hydrogen and acetyl and R^2 is
20 selected from the group consisting of OH and NH_2 .

14. A peptide of Claim 13 wherein R^2 is NH_2 .

15. A biologically active peptide of Claim 1 selected from the group comprising:

25 (SEQ ID NO:1) Cys-Leu-Lys-Lys-Lys-His-Ala-Leu-Cys-Tyr-
 NH_2 ;
 (SEQ ID NO:2) Cys-Ser-Lys-Lys-Lys-Leu-Ala-Leu-Cys-Tyr-
 NH_2 ;
 (SEQ ID NO:3) Cys-His-Lys-Leu-Lys-Ala-Ala-Leu-Cys-Tyr-
 NH_2 ;

- 43 -

- (SEQ ID NO:4) cyclo-(Cys-Leu-Lys-Lys-Lys-His-Ala-Leu-Cys)-Tyr-NH₂;
- 5 (SEQ ID NO:5) cyclo-(Cys-Ser-Lys-Lys-Lys-Leu-Ala-Leu-Cys)-Tyr-NH₂;
and
- (SEQ ID NO:6) cyclo-(Cys-His-Lys-Leu-Lys-Ala-Ala-Leu-Cys)-Tyr-NH₂;
- (SEQ ID NO:7) Ac-Phe-Lys-Lys-Lys-Leu-Ala-Ley-Cys-Tyr-NH₂;
- 10 (SEQ ID NO:8) Phe-Lys-Lys-Lys-Leu-Ala-Ley-Cys-Tyr-NH₂;
- (SEQ ID NO:9) Ac-His-Lys-Lys-Lys-Leu-Ala-Ley-Cys-Tyr-NH₂;
- (SEQ ID NO:10) His-Lys-Lys-Lys-Leu-Ala-Ley-Cys-Tyr-NH₂;
- (SEQ ID NO:11) Leu-Lys-Lys-Lys-His-Ala-Leu-Cys-Tyr-NH₂;
- 15 (SEQ ID NO:12) Ac-Leu-Lys-Lys-Lys-Leu-Ala-Leu-Cys-Tyr-NH₂;
- (SEQ ID NO:13) Leu-Lys-Lys-Lys-Leu-Ala-Leu-Cys-Tyr-NH₂;
- (SEQ ID NO:14) Ac-Asn-Lys-Lys-Lys-Leu-Ala-Leu-Cys-Tyr-NH₂;
- 20 (SEQ ID NO:15) Asn-Lys-Lys-Lys-Leu-Ala-Leu-Cys-Tyr-NH₂;
- (SEQ ID NO:16) Pro-Lys-Lys-Lys-Leu-Ala-Leu-Cys-Tyr-NH₂;
- (SEQ ID NO:17) Gln-Lys-Lys-Lys-Leu-Ala-Leu-Cys-Tyr-NH₂;
- (SEQ ID NO:18) Ser-His-Lys-Lys-Leu-Ala-Leu-Cys-Tyr-NH₂;
- 25 (SEQ ID NO:19) Ac-Ser-Lys-Ala-Lys-Leu-Ala-Leu-Cys-Tyr-NH₂;
- (SEQ ID NO:20) Ser-Lys-Phe-Lys-Leu-Ala-Leu-Cys-Tyr-NH₂;

16. A pharmaceutical composition comprising at least one peptide of claim 1 in an amount effective to inhibit cellular adherence and a pharmaceutically acceptable carrier or diluent.

30

17. A method for inhibiting leukocyte adherence in a host comprising the step of administering to said host at least one peptide of Claim 1 in an amount effective to inhibit leukocyte adherence.

5 18. A method for modifying binding of a selectin in a host comprising administering to said host at least one peptide of Claim 1 in an amount effective to inhibit cellular adherence.

10 19. The method of Claim 16 wherein said selectin is selected from the group consisting of P-selectin, E-selectin and L-selectin.

20. A method for decreasing inflammation in a host comprising administering to said host at least one peptide of claim 1 in an amount effective to decrease inflammation.

15 21. A method for decreasing coagulation in a host comprising administering to said host at least one peptide of claim 1 in an amount effective to decrease coagulation.

20 22. A method for treating a host having a condition selected from the group consisting of ischemia and reperfusion, bacterial sepsis and disseminated intravascular coagulation, adult respiratory distress syndrome, tumor metastasis, rheumatoid arthritis and atherosclerosis, comprising administering to said host at least one biologically active peptide of claim 1 in an
25 amount effective to treat said condition.

23. A method of detecting defective selectin-binding ligands and/or defective integrin-binding ligands in a host comprising the steps of:

30 (a) taking a sample of the cells to be tested from said host;

- 47 -

(b) contacting said cells to be tested with a labeled peptide of Claim 1; and

(c) assessing the binding of said labeled peptide to said cell to be tested.

5 24. The method of Claim 23 wherein said cells to be tested are leukocytes.

 25. A method of detecting high concentrations or elevated localized concentrations of selectin binding cells and/or integrin binding cells in a host comprising the
10 steps of:

 (a) administering to said host a labeled peptide of Claim 1;

 (b) withdrawing a sample of cells from said host; and

15 (c) assessing the binding of said labeled peptide to said sample of cells.

 26. The method of Claim 25 wherein said cells are leukocytes.

20 27. The method of Claim 25 wherein said cells are tumor cells.

 28. The method of Claim 25 wherein said peptide is labeled with a moiety selected from the group comprising radioactive tracers, fluorescent tags, enzymes, and
25 electron-dense materials.

 29. A method of preparing a peptide of Claim 1 comprising adding amino acids either singly or in pre-formed blocks of amino acids to an appropriately functionalized solid support.

30 30. A method of preparing a peptide of Claim 1 comprising adding amino acids either singly or in preformed

blocks in solution or suspension by chemical ligation techniques.

5 31. A method of preparing a peptide of Claim 1 comprising adding amino acids either singly or in preformed blocks in solution or suspension by enzymatic ligation techniques.

10 32. A method of preparing a peptide of Claim 1 comprising enzymatically by inserting nucleic acids encoding the peptide into an expression vector, expressing the DNA, and translating the DNA into the peptide.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US93/12110

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:
(Telephone Practice)
Please See Extra Sheet.

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
1-22, 29-31

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
☐ No protest accompanied the payment of additional search fees.

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept. In order for all inventions to be examined, the appropriate additional examination fees must be paid.

Group I, claims 1-22 and 29-31, drawn to peptides, pharmaceutical compositions, methods of treatment and methods of solid and liquid phase peptide synthesis, classified in Class 514, subclass 12.

Group II, claims 23 and 24, drawn to an in vitro method for detecting defective selectin-binding ligands, classified in Class 435, subclass 7.1.

Group III, claims 25-28, drawn to an in vivo diagnostic method, classified in Class 424, subclass 9.

Group IV, claim 32, drawn to a recombinant method of peptide synthesis, classified in Class 435, subclass 69.1.

The inventions listed as Groups I-IV do not meet the requirements for Unity of Invention for the following reasons: The Groups are not so linked by a special technical feature within the meaning of PCT Rule 13.2 so as to form a single inventive concept. Specifically, the groups are directed to different methods practiced with materially different process steps for materially different purposes. Note that PCT Rule 13 does not provide for multiple methods within a single application.

ALZHEIMER'S DISEASE THERAPEUTICS

The field of the invention is Alzheimer's disease therapeutics.

5 Background of the Invention

Alzheimer's disease (AD) is a progressive degenerative disorder of the brain that afflicts over four million people in the United States. No effective treatment is available. The most characteristic change
10 observed upon post-mortem histopathological analysis of AD-afflicted brain tissue is the presence of neuritic and cerebrovascular plaques containing dense deposits of β -amyloid protein (Selkoe, Cell 58:611-612, 1989). β -amyloid is a 39-43 amino acid peptide (Glenner and Wong,
15 biochem. biophys. Res. Commun. 120:885-890, 1984; Masters et al., Proc. Natl. Acad. Sci. USA 82:4345-4249, 1985) synthesized as part of a larger precursor protein referred to as amyloid precursor protein (APP), which is known to have a number of isoforms in humans (APP₆₉₅, Kang
20 et al., Nature 325:733-736, 1987; APP₇₅₁, Ponte et al., Nature 331:525-527, 1988, and Tanzi et al., Nature 331:528-530, 1988; and APP₇₇₀, Kitaguchi et al., Nature 331:530-532, 1988). The amino terminal of β -amyloid is generated by cleavage of a peptide bond of APP which in
25 APP₆₉₅ lies between Met596 and Asp597.

Although structural alterations of APP are implicated in the pathogenesis of Alzheimer's disease, it remains unknown how they cause the disease. No biological function for APP has been identified, although
30 there is evidence that APP has a receptor-like architecture (Kang et al., Nature 325:733-736, 1987; Ponte et al., Nature 331:525-527, 1988; Tanzi et al., Nature 331:528-530, 1988; Kitaguchi et al., Nature 331:530-532, 1988), is located on the neuronal surface
35 (Dyrks et al., EMBO J. 7:949-957, 1988), and possesses an

- 2 -

evolutionarily conserved cytoplasmic domain (Yamada et al., Biochem. Biophys. Res. Commun. 149:665-671, 1987).

Summary of the Invention

The methods and therapeutical compositions of the invention are based upon the discovery, described in detail below, that APP forms a complex with G_o , a major GTP-binding protein (or "G protein") in brain. Like all G proteins, a molecule of G_o is made up of one α subunit and one $\beta\gamma$ subunit. Two isoforms of G_o , known as G_{o1} (or G_{oA}) and G_{o2} (or G_{oB}), have been identified; they have slight amino acid differences in their α subunits, and are together referred to herein as G_o . The cDNA sequence and deduced amino acid sequence of the α subunits of each of G_{o1} and G_{o2} (as reported by Strathmann et al., Proc. Natl. Acad. Sci. USA 87:6477-6481, 1990) are shown in Fig. 4a (SEQ ID NO: 2) and Fig. 4b (SEQ ID NO: 28), respectively.

The finding that APP associates with G_o is consistent with related findings concerning other G proteins, as disclosed in a second application (USSN _____) having the same inventor and filing date as the present application, which second application is herein incorporated by reference. The cytoplasmic APP₆₉₅ sequence His⁶⁵⁷-Lys⁶⁷⁶ (SEQ ID NO: 1) possesses a specific G_o -activating function, and is necessary for complex formation of this APP with G_o ; this sequence, sometimes referred to as the "couplone" region of APP, is completely conserved in APP₇₅₁ and APP₇₇₀, as well as in mouse APP₆₉₅. This provides evidence that APP is a receptor coupled to G_o , and suggests that abnormal APP- G_o signalling is involved in the Alzheimer's disease process.

- 3 -

The invention includes a method of identifying a therapeutic useful for treating or preventing Alzheimer's disease, which method includes the steps of

contacting (a) a first molecule containing the
5 couplone portion of APP (SEQ ID NO: 1) with (b) a second
molecule containing the amino acid sequence of G_o (SEQ ID
NO: 2) or an APP-associating region of G_o (SEQ ID NOS: 3,
4, or 5), in the presence of a candidate compound; and
either (i) determining whether the candidate
10 compound interferes with (i.e., inhibits partially or
completely) the association of the first and second
molecules, or (ii) determining whether the candidate
compound interferes with the activation of the second
molecule by the first molecule, such interference being
15 an indication that the candidate compound is a potential
therapeutic useful for treating or preventing Alzheimer's
disease. The determining step may be accomplished by,
for example, immunoprecipitating the first molecule with
an antibody specific for APP, and detecting the presence
20 or amount of the second molecule which co-precipitates
with the first molecule. Alternatively, the second
molecule can be immunoprecipitated with an antibody
specific for G_o, following which the presence or amount
of the first molecule which co-precipitates with the
25 second molecule is determined. Where activation is the
criterion being measured, the determination step may be
accomplished by contacting the second molecule with a
substrate which is or includes GTP or an analog of GTP
[such as GTP γ S or Gpp(NH)p], and detecting or measuring
30 the binding of the substrate to the second molecule,
wherein such binding is evidence of activation of the
second molecule by the first molecule. In preferred
embodiments, the contacting step is carried out in a
cell-free system; the Mg²⁺ concentration at which the
35 contacting step is carried out is between approximately

- 4 -

1x10⁻⁷ and 1x10⁻² M, and the first molecule includes the cytoplasmic tail portion of APP₆₉₅ from residues 649 to 695 (SEQ ID NO: 6) and/or the membrane-spanning portion of APP₆₉₅ from residues 639 to 648 (SEQ ID NO: 7) (the entire membrane-spanning segment of APP₆₉₅ being from residues 625 to 648, SEQ ID NO: 8); the first molecule more preferably includes substantially all of APP (SEQ ID NO: 9). (Alternatively, the corresponding functional regions of APP₇₅₁ or APP₇₇₀, or any other APP, may be used.) The second molecule preferably contains two or three of the putative APP-associating regions referred to above, and may also contain one or more of the GTP-binding regions of G_o, corresponding to residues 35 to 50 (SEQ ID NO: 10), residues 201 to 218 (SEQ ID NO: 29), or residues 263 to 274 (SEQ ID NO: 30) of G_{o1} [Kaziro, "Structure of the genes coding for the α subunits of G proteins", Ch. 1 in ADP-ribosylating Toxins and G proteins (Moss, J., and Vaughan, M. eds.) pp189-206, American society for Microbiology, Washington, D.C. (1988)], and more preferably contains substantially all of G_o (SEQ ID NO: 2).

The invention also includes a system (e.g., a cell-free *in vitro* system) for screening candidate Alzheimer's disease therapeutics, which system includes a first polypeptide containing a sequence essentially identical to that of peptide 20 (SEQ ID NO: 1), and a second polypeptide containing a sequence essentially identical to one, two or three of the putative APP-associating regions of G_o (SEQ ID NOs: 3, 4, and 5); the system may also include a means for detecting either (a) the association of the first polypeptide with the second polypeptide, or (b) the activation of the second polypeptide by the first polypeptide. The first polypeptide may conveniently be anchored to a solid material (e.g., a cellular membrane, a polystyrene

- 5 -

surface, or a standard matrix material), or may be in a phospholipid vesicle. It may include a sequence essentially identical to the membrane-spanning region of APP, and/or a sequence essentially identical to the entire cytoplasmic tail of APP. The second molecule preferably contains the GTP-binding domain of G_o , and more preferably contains the entire sequence of G_o .

The invention also features a method for diminishing the activation of G_o in a neuronal cell by treating the cell with a compound, such as a peptide fragment of G_o or of the cytoplasmic tail of APP, which blocks association of neuronal G_o with, and/or activation of neuronal G_o by, the cytoplasmic tail of APP. The cell may be so treated *in vivo* (i.e., in an animal, e.g. a mammal such as a human or other primate, cow, horse, pig, sheep, goat, dog, cat, rat, mouse, guinea pig, hamster, or rabbit) or *in vitro*. This method may be used to prevent or treat the symptoms of Alzheimer's disease in a patient. Such a compound may include, for example, a peptide having fewer than 50 amino acids (preferably 40 or fewer, and more preferably 30 or fewer), and containing the sequence of peptide 20. Also within the invention is a DNA molecule (e.g., a plasmid or viral DNA) encoding such a peptide, and a therapeutic composition containing, in a pharmaceutically acceptable carrier, either the peptide or the DNA molecule.

In another aspect, the invention features a method for identifying a ligand for which APP is a receptor, which method includes the steps of

- providing an APP molecule, the cytoplasmic tail of which is accessible to a molecule of G_o ;
- contacting a candidate compound with the extracellular domain of the APP molecule; and
- detecting either (a) association of G_o with the APP molecule, (b) dissociation of G_o from the APP

- 6 -

molecule, or (c) activation of G_o by the APP molecule, such association, dissociation, or activation being evidence that the candidate compound is a ligand of APP.

Other features and advantages of the invention
5 will be apparent from the detailed description set forth below, and from the claims.

Brief Description of the Drawings

Fig. 1(a) is a schematic diagram illustrating the structural organization of APP. The hatched box contains
10 the sequence of the β/A_4 protein; the black box contains the so-called "Peptide 20" or couplone sequence; filled circles are N-glycosylation sites. The numbers designate amino acid sequence numbers corresponding to APP₆₉₅.

Fig. 1(b) is a bar graph illustrating the effects
15 of synthetic APP peptides on G_o . In (b), (d), (e) and (f), values represent the mean \pm S.E. of three experiments.

Fig. 1(c) is a graph illustrating the time course of the action of peptide 20 on G_o . Values represent the
20 mean of three experiments. Since the S.E. was $< 5\%$ of each value in this figure, the error bars are not indicated.

Fig. 1(d) is a graph illustrating the effects of peptide 20 variants on G_o .

25 Fig. 1(e) is a graph illustrating the effect linkage with a transmembrane region has on the action of peptide 20 on G_o .

Fig. 1(f) is a graph illustrating the effect of pertussis toxin on peptide 20-induced stimulation of GTP-
30 γ S binding to G_o .

Figs. 2a-2d is a set of SDS-PAGE gels analyzed by immunoblotting, which illustrate the immunoprecipitation of APP and G_o by an anti-APP antibody from brain membranes. (a) Immunoprecipitation of APP by 22C11.

(b) Immunoprecipitation of G_o by 22C11. (c) Effect of Mg^{2+} on the immunoprecipitation of G_o by 22C11.

(d) Effect of peptide 20 on 22C11-induced precipitation of $G_{o\alpha}$ (left) and APP (right). Each of the results presented in this figure was reproduced at least three times.

Fig. 3a is a schematic diagram of the construction method used to prepare recombinant mutant APP cDNAs. Regions labeled ATG, TAA, TGA signify original translation and termination sites and a newly inserted termination site, respectively.

Fig. 3b is a schematic diagram comparing the structures of authentic APP₆₉₅ and the two recombinant mutant APP polypeptides, ΔN and ΔC .

Fig. 3c is an immunoblot analysis of Sf9 membranes using anti-Alz 90, 1C1, and 4G5.

Fig. 3d is an immunoblot analysis of the 22C11-precipitate from an Sf9 membrane- G_o reconstitution mixture.

Fig. 3e is an immunoblot illustrating dissociation of G_o from APP by activation of G_o . Each of the results presented in Figs. 3c-e was reproduced at least three times.

Fig. 4a is the cDNA sequence and deduced amino acid sequence of $G_{o1\alpha}$ (Strathmann et al., Proc. Natl. Acad. Sci. USA 87:6477-6481, 1990) (SEQ ID NO: 2).

Fig. 4b is the cDNA sequence and deduced amino acid sequence of $G_{o2\alpha}$ (Strathmann et al.) (SEQ ID NO: 28).

Detailed Description

It was previously shown that the insulin-like growth factor II receptor (IGF-IIR) couples directly to the G protein referred to as G_i (Nishimoto et al., J. Biol. Chem. 264:14029-14038, 1989) via a 14-residue section of the cytoplasmic tail of IGF-IIR, Arg²⁴¹⁰-Lys²⁴²³

- 8 -

(Okamoto et al., Cell 62:709-717, 1990; Okamoto et al., Proc. Natl. Acad. Sci. U.S.A. 88:8020-8023, 1991). The structural determinants for the G_i-activating function in IGF-IIR were defined as (i) two basic residues at the N-terminal region of the amino acid sequence, and (ii) a C-terminal motif of B-B-X-B or B-B-X-X-B (where B is a basic residue and X is a non-basic residue) (Okamoto et al., Cell 62:709-717, 1990). To assess whether APP might function as a G protein-coupled receptor, the amino acid sequence of human APP₆₉₅ was examined for regions of less than 26 residues which satisfy (i) and (ii). The sequence His⁶⁵⁷-Lys⁶⁷⁶ is the only such region in the cytoplasmic domain of APP₆₉₅. In two other isoforms of APP, APP₇₅₁ (Ponte et al., Nature 331:525-527, 1988; Tanzi et al., Nature 331:528-530, 1988) and APP₇₇₀ (Kitaguchi et al., Nature 331:530-532, 1988), as well as in mouse APP₆₉₅ (Yamada et al., Biochem. Biophys. Res. Commun. 149:665-671, 1987), this sequence is completely conserved.

Preparation of peptides

A peptide corresponding to the His⁶⁵⁷-Lys⁶⁷⁶ region of APP [HHGVVEVDAAVTPEERHLSK (SEQ ID NO: 1)] was synthesized and purified by standard methods using solid phase synthesis; this peptide is referred to as "peptide 20". Similarly prepared were peptides corresponding to other regions of APP₆₉₅: APP(1-10), MLPGLALLLL (SEQ ID NO: 11); APP(597-606), DAEFRHDSGY (SEQ ID NO: 12); APP(677-695), MQQNGYENPTYKFFEQMQN (SEQ ID NO: 13); and APP(639-648), TVIVITLVML (SEQ ID NO: 7), a portion of the transmembrane region of APP; as well as the following variants of peptide 20: HGVVEVDAAVTPEERHLSK (H-deleted, SEQ ID NO: 14); GVVEVDAAVTPEERHLSK (HH-deleted, SEQ ID NO: 15); HHGVVEVDAAVTPEE (RHLSK-deleted, SEQ ID NO: 16);

- 9 -

KQYTSIHGVEVDAAVTPEERHLSK (KQYTSI-added, SEQ ID NO: 17); and TVIVITLVMLHGVEVDAAVTPEERHLSK (transmembrane region-connected peptide 20; SEQ ID NO: 18).

Peptides were purified by HPLC to greater than 95%
5 purity, and were used immediately after synthesis.

Materials and Methods.

Trimeric G_o was purified to homogeneity from bovine brain as described (Katada et al., FEBS Lett. 213:353-358, 1987). This G_o preparation was stored in 20
10 mM Hepes/NaOH (pH 7.4), 1 mM EDTA, and 0.7% CHAPS, and diluted ≥ 10 fold for assays. $G_{i3\alpha}$, which was used in combination with 1.5-fold concentrated $G\beta\gamma$ (Okamoto et al., Natl. Acad. Sci. U.S.A. 88:8020-8023, 1991), was prepared as described by Morishita et al., Biochim.
15 Biophys. Acta 161:1280-1285, 1989. Low molecular weight G proteins were prepared as described by Matsui et al., J. Biol. Chem. 263:11071-4, 1988; $G\beta\gamma$ was purified from bovine brain as set forth in Katada et al., FEBS Lett. 213:353-358, 1987.

20 GTP γ S binding to G_o was assayed in a buffer containing 50 mM Hepes/NaOH (pH 7.4), 100 μ M EDTA, 120 μ M $MgCl_2$, and 60 nM [35 S]GTP γ S (DuPont-New England Nuclear) at 37°C, and the fraction of total G_o bound to GTP γ S was measured as described (Okamoto et al., Cell 62:709-717,
25 1990). GTP γ S binding to peptides was negligible. The total amount of G_o in a given preparation was defined as the saturation amount of GTP γ S bound to G_o following a 30-min incubation of G_o with 10 mM Mg^{2+} and ≥ 60 nM GTP γ S at 30°C.

30 Reconstitution of G_o into phospholipid vesicles was accomplished with 1 mg/ml of phosphatidylcholine, using the gel filtration method (Nishimoto et al., J. Biol. Chem. 264:14029-14038, 1989). In a final

- 10 -

incubation for GTP γ S binding, 5 nM of reconstituted G_o was used.

For experiments exploring the effect of Mg²⁺, the Mg²⁺ concentration was set by using Mg-EDTA buffer (Birnbaumer et al., J. Eur. J. Biochem. 136:107-112, 1983).

Bovine brain membranes, prepared as described (Katada et al., FEBS Lett. 213:353-358, 1987) and suspended in buffer A [10 mM Hepes/NaOH (pH 7.4), 1 mM EDTA, 10 mM acetic acid, and 250 mM sucrose, plus a mixture (termed "PAL") of 2 mM PMSF, 20 μ g/ml aprotinin, and 20 μ M leupeptin], were centrifuged and the pellet was solubilized for 1 h at 4°C in buffer B (10 mM Hepes/NaOH (pH 7.4), 1 mM EDTA, 120 mM NaCl, 0.5% CHAPS, and PAL). Following centrifugation of the material at 15000 rpm for 1 h, the supernatant (500 μ g protein, unless specified) was incubated in buffer C (20 mM Hepes/NaOH (pH 7.4), 1 mM EDTA, 120 mM NaCl, and PAL) and 2% BSA with 22C11-coated protein G-Sepharose, which had been prepared by incubating protein G-Sepharose (Pharmacia) with anti-APP monoclonal antibody 22C11 (Boehringer Mannheim) for 1 h at 4°C. An antibody concentration of ≥ 2 μ g/ml was found to saturate precipitation of APP and G_o, so 2 μ g/ml was the concentration used for immunoprecipitation studies. As a control, 2 μ g/ml of rabbit IgG was used. After overnight shaking at 4°C, the immunoprecipitated sample was centrifuged at 5000 rpm for 5 min. The pellet was washed three times with ice-cold buffer C and the final pellet was applied to SDS-PAGE. Electrophoretic transfer onto a PVDF sheet was performed as described (Okamoto et al., J. Biol. Chem. 266:1085-1091, 1991). After blocking with PBS containing 2% skim milk and 1% BSA, the sheet was incubated with the first antibody [1 μ g/ml of 22C11; 1/1000 dilution of anti-G_o α monoclonal antibody GC/2 (DuPont-New England Nuclear); 1/1000 dilution of 1C1, a

- 11 -

monoclonal antibody against the C-terminal peptide 677-695 of APP₆₉₅] for 4 h, and then exposed to horseradish peroxidase-conjugated goat IgG reactive for mouse or rabbit immunoglobulins for 2-4 h at room temperature.

- 5 The antigenic bands were detected with an ECL detection kit (Amersham). YL1/2 (SERA Lab), an anti-tubulin antibody, was used at 1:500 dilution for immunodetection.

Effects of synthetic APP peptides on G proteins.

- In the experiment shown in Fig. 1(b), 10 nM G_o was
 10 incubated with water or 100 μM of each peptide for 2 min, and the amount of GTPγS bound to G_o at the end of this period was measured. In the experiment shown in Fig. 1(c), 10nM G_o was incubated with water (○) or 100 μM peptide 20 (SEQ ID NO: 1) (●), and GTPγS binding was
 15 measured at the indicated times. From Fig. 1(d), it can be seen that peptide 20 (SEQ ID NO: 1) stimulated the rate constant of GTPγS binding to G_o in a dose-dependent manner, whereas Fig. 1(b) shows that peptides from other regions of APP₆₉₅ were ineffective. GTPγS binding to G_o
 20 in the presence or absence of peptide 20 (SEQ ID NO: 1) obeyed first-order kinetics according to the equation

$$\ln [(BT-B)/BT] = -k_{app}t$$

- (B is the binding at time t; BT is the total binding observable at infinite time; and k_{app} is the rate constant
 25 for GTPγS binding). The ability of peptide 20 (SEQ ID NO: 1) to activate G_o was gradually decreased during storage at either -4°C or -20°C.

- Studies using structural variant peptides suggest that both the N-terminal basic residues and the C-
 30 terminal B-B-X-X-B motif play essential roles in the G_o-activating function of peptide 20 (SEQ ID NO: 1) [Fig. 1(d)]. In this experiment, 10 nM G_o was incubated with various concentrations of HHGVVEVDAAVTPEERHLSK (peptide 20, SEQ ID NO: 1; □), HGVVEVDAAVTPEERHLSK (H-deleted, SEQ

- 12 -

ID NO: 14; ◇), GVVEVDAAVTPEERHLSK (HH-deleted, SEQ ID NO: 15; □), HHGVVEVDAAVTPEE (RHLSK-deleted, SEQ ID NO: 16; ◆), or KQYTSIHGGVVEVDAAVTPEERHLSK (KQYTSI-added, SEQ ID NO: 17; ■), and GTPγS binding to G_o at 2 min. was measured. Fig. 1(d) indicates which aspects of primary structure determine the G_o-activator function of peptide 20 (SEQ ID NO: 1). Deletion of either one or both of the N-terminal His residues nullified G_o-activator function of the peptide. The peptide (SEQ ID NO: 16) in which the C-terminal five residues of peptide 20 (SEQ ID NO: 1) has been deleted is several times less potent than peptide 20 (SEQ ID NO: 1).

As illustrated in Fig. 1(e), G_o reconstituted in phospholipid vesicles was incubated with transmembrane region-connected peptide 20 (TVIVITLVMLHHGVVEVDAAVTPEERHLSK, SEQ ID NO: 18; □) or the partial sequence of the APP transmembrane domain alone (TVIVITLVML, SEQ ID NO: 7; □). Transmembrane region-connected peptide 20 (SEQ ID NO: 18) was also incubated with G_o in the absence of phospholipids and the presence of 0.07% CHAPS (◆). The transmembrane region-connected peptide 20 (SEQ ID NO: 18) stimulated G_o reconstituted in phospholipid vesicles with a potency 10 times greater than that of peptide 20 (SEQ ID NO: 1). The transmembrane region alone (SEQ ID NO: 7) was without effect on G_o. In the absence of phospholipids, transmembrane region-connected peptide 20 (SEQ ID NO: 18) showed an effect on G_o no more potent than peptide 20 (SEQ ID NO: 1). Therefore, the stimulatory action of this transmembrane region-connected peptide (SEQ ID NO: 18) is attributed to the peptide 20 (SEQ ID NO: 1) sequence; the potentiating effect of the transmembrane region may be exerted by interactions with phospholipids.

In the experiment shown in Fig. 1(f), ADP-ribosylation of G_o was accomplished by incubating G_o

- 13 -

reconstituted in phospholipid vesicles with 10 μ g/ml preactivated pertussis toxin in the presence of 10 μ M NAD for 15 min at 30°C as described (Okamoto et al., Cell 62:709-717, 1990). Preactivation of pertussis toxin (Funakoshi, Japan) was carried out by treating the toxin with 100 μ M ATP and 1 mM DTT for 10 min at 30°C. Reconstitution of G_o into phospholipid vesicles was accomplished with 1 mg/ml phosphatidylcholine (Sigman, P-5638) at a final G_o concentration of 50.2 nM in a buffer containing 20 mM Hepes/NaOH (pH 7.4), 0.1 mM EDTA, 1 mM DTT, and 100 mM NaCl by the gel filtration method (Nishimoto et al., J. Biol. Chem. 264:14029-14038, 1989). In a final incubation for GTP γ S binding, 5 nM of reconstituted G_o was used. Increasing concentrations of peptide 20 (SEQ ID NO: 1) were incubated for 2 min with G_o reconstituted in phospholipid vesicles which had been treated with pertussis toxin in the presence (\blacklozenge) or absence (\square) of NAD, and GTP γ S binding to G_o was measured.

Although peptide 20 (SEQ ID NO: 1) produced 2-3 fold stimulation of GTP γ S binding to G_o in the mid-range of Mg^{2+} concentrations, the effect of peptide 20 (SEQ ID NO: 1) could not be observed at low (\leq 100 nM) or high (\geq 10 mM) Mg^{2+} concentrations.

Peptide 20 (SEQ ID NO: 1) had little effect on G proteins other than G_o : G_{i1} , G_{i2} , G_{i3} , G_s , c-Ki-ras p21 and smg p25A were not stimulated by this peptide (data not shown). Thus, peptide 20 (SEQ ID NO: 1) activates G_o in a receptor-like manner, suggesting that APP interacts directly with G_o through the peptide 20 (SEQ ID NO: 1) region.

Coprecipitation of APP and G_o

In an effort to determine whether APP is linked to G_o in a native membrane environment, the coprecipitation studies shown in Fig. 2a were performed. Solubilized membranes of bovine brain were first immunoprecipitated

- 14 -

by monoclonal anti-APP antibody 22C11, and the immunoprecipitate was then probed by immunodetection with 22C11 (Lane 2) or 1C1, a monoclonal antibody against the C-terminal peptide₆₇₇₋₆₉₅ of APP (SEQ ID NO: 13; Lane 4).
5 Lanes 1 and 3 of Fig. 2a indicate the controls in which either no solubilized membranes were included (Lane 1), or rabbit IgG was used for the precipitation step instead of antibody 22C11 (Lane 3). In each control, immunodetection was performed with 22C11. The 55-kDa and
10 25-kDa bands seen in Lanes 1 and 2 may be heavy and light chains of the 22C11 used for precipitation, which reacted with an anti-mouse IgG antibody during immunodetection. The precipitate by control rabbit IgG contained no detectable APP. Although the 100 kD molecular size of
15 APP appears here to be slightly less than the 110-130 kD reported (Weidemann et al., Cell 57:115-126, 1989), the precipitated form is unlikely to be an extracellular fragment of APP, because 1C1 recognizes this 100-kDa band.

20 In the experiment illustrated in Fig. 2b, coprecipitation of various G proteins with APP was investigated. Bovine brain membrane preparations were immunoprecipitated with 22C11; the immunoprecipitated proteins were subjected to SDS-PAGE and immunoblotted
25 with the indicated anti-G protein antisera (1/1000 dilution). Lane 2: GC/2, anti-G_oα antiserum; lane 3: GC/2 plus 1 μg/ml of purified G_o; lane 4: GA/1, common Gα antiserum; lane 5: AS/7, anti-Giα antiserum; lane 6: MS/1, common Gβ antiserum. Lane 1 shows a control
30 immunoblot with GC/2, in which a buffer solution rather than the bovine brain membrane preparation was immunoprecipitated with 22C11. Lane 7 indicates immunoblotting with GC/2 of the precipitate resulting from immunoprecipitation of brain membranes with control
35 rabbit IgG, rather than 22C11. The identity of the 39-

- 15 -

kDa protein in lane 2 as G_o was verified by its absence in the non-membrane control (lane 1); by its staining with another $G_o\alpha$ -specific antibody, $\alpha GO1$ (Morishita et al., Eur. J. Biochem. 174:7-94, 1988) (data not shown);

5 and by a diminution of staining of this band in the presence of excess soluble G_o (lane 3). The 22C11-precipitate also contained immunoreactivity of $G\beta$ in a doublet at 35-36-kDa (lane 6). The 22C11-precipitate did not react with an anti- $G_{i\alpha}$ antibody AS/7 (lane 5). The

10 antibody GA/1 detected only a 39-kDa band in the 22C11-precipitate (lane 4). The control rabbit IgG immunoprecipitate did not produce anti- G_o -immunoreactive bands corresponding to either APP or G_o (lane 7). These experiments indicate that the 22C11-precipitate from

15 brain membranes contains APP immunoreactivity at 100 kDa, $G_o\alpha$ immunoreactivity at 39 kDa, and $G\beta$ immunoreactivity in a doublet at 35-36 kDa, but no detectable immunoreactivity indicating the presence of $G_{i\alpha}$ or other heterotrimeric G proteins. A tubulin antibody, YL1/2,

20 did not stain the 22C11-precipitate (data not shown).

In the experiment shown in Fig. 2c, the effect of Mg^{2+} concentration on co-precipitation of G_o with anti-APP antibody was studied. 100 μ g of solubilized brain membranes were precipitated by 22C11 in the presence of

25 various Mg^{2+} concentrations controlled with Mg-EDTA buffer (Birnbaumer et al., J. Eur. J. Biochem. 136:107-112, 1983). The precipitates were analyzed by immunoblotting with GC/2. The control lane indicates the results of precipitation of brain membranes by rabbit IgG followed

30 by immunodetection with GC/2. In the absence of Mg^{2+} , G_o was less efficiently co-precipitated by 22C11. Mg^{2+} concentrations between 1 μ M and 1 mM resulted in maximal immunoprecipitation of G_o . At concentrations > 10 mM, relatively little G_o was precipitated. In contrast,

35 immunoprecipitation of APP by 22C11 was not affected by

- 16 -

Mg²⁺ concentration (data not shown). These results indicate that, while Mg²⁺ is not absolutely required for complex formation by APP and G_o, the concentration of Mg²⁺ does strongly influence complex formation. A mid range of Mg²⁺ concentration was found to facilitate APP-G_o association.

Fig. 2d illustrates the results of an experiment indicating that peptide 20 (SEQ ID NO: 1) prevents the 22C11-mediated co-precipitation of G_o, whereas it did not affect the precipitation of APP by 22C11. In contrast, a control peptide (SEQ ID NO: 13) representing a segment of APP different from that represented by peptide 20 (SEQ ID NO: 1) had no discernable effect on 22C11-mediated co-precipitation of G_o. In this experiment, solubilized brain membranes were incubated with 22C11-coated beads in the presence of 10 μM peptide 20 (SEQ ID NO: 1; 2nd and 5th lanes) or 10 μM of the control peptide, peptide₆₇₇₋₆₉₅ of APP (SEQ ID NO: 13; 3rd and 6th lanes), or in the absence of both of these peptides (1st and 4th lanes). In this experiment, an anti-mouse IgG antibody different from that used in (a) was employed.

Precipitation of G_o reconstituted with recombinant APP-antibody complex

A baculovirus DNA encoding full-length APP₆₉₅ (SEQ ID NO: 9) was prepared as outlined in Fig. 3a. Authentic mouse APP₆₉₅ cDNA (SEQ ID NO: 9) was provided by Dr. Yoshiyuki Sakaki (University of Tokyo, Japan) (Yamada et al., Biochem. Biophys. Res. Commun. 149:665-671, 1987) in the vector pUC18. The HindIII-BamHI fragment containing the entire coding region was initially subcloned into the vector pBR322 (pBR-APP). A single BamHI site was inserted immediately before the ATG codon of the HindIII-SphI fragment. This BamHI site was inserted to permit efficient expression of the encoded APP protein in

- 17 -

baculovirus-infected cells. The BamHI site-inserted APP₆₉₅-coding DNA (BamHI-APP₆₉₅) was constructed from the HindIII-SphI fragment and pBR-APP, utilizing their internal KpnI sites, and subcloned into pUC18. By using BamHI-APP₆₉₅ as template, two truncation mutants were generated and subcloned into pUC18. These mutants possess an insertion of two TGA codons immediately before (ΔN) or after (ΔC) the peptide 20 sequence. Each BamHI-BamHI fragment of these respective APP-variation-encoding pUC18 plasmids was inserted into the baculovirus transfer/expression vector pVL1393 (Invitrogen). The entire region that had been through a single-stranded intermediate was sequenced to confirm the absence of unwanted nucleotide changes. New insertions were generated by oligonucleotide-directed mutagenesis with a kit (Takara) by the method of Kunkel et al. (Meth. Enzymol. 154:367-382, 1987). For the insertion of a BamHI site, a restriction fragment encoding the ATG start codon was subcloned into the vector M13mp18 and a single stranded template was generated. An oligonucleotide primer (CCACGCAGGATCACGGGATCCATGCTGCCCAGCTTG; SEQ ID NO: 19) was used to introduce GGATCC (SEQ ID NO: 20) immediately before the start codon. Following primer extension, the phage was used to transform E. coli strain JM109. Plaques were selected and single stranded DNA was sequenced. A restriction fragment containing the mutated region was subcloned into pBR-APP. For the insertion of the stop codons, oligonucleotide primers [CAGTACACATCCATCTGATGACATCATGGCGTGGTG (SEQ ID NO: 21) and CGCCATCTCTCCAGTGATGAATGCAGCAGAACGGA (SEQ ID NO: 22)] and the M13mp19 vector were used to introduce two sequential TGA stop codons. Using the method of Summers and Smith (Summers et al., Tex. Agric. Exp. Stn. Bull. 1555, 1987), baculoviruses incorporating these APP cDNAs were generated using selection by immunoblot analysis with

- 18 -

22C11, and recovered by infecting Sf9 cells (Invitrogen). Four days after treatment of Sf9 cells with the viruses, cells were homogenized and suspended in buffer A. After the solubilization of the pellet with buffer B, the

5 supernatant (100 μ g) was mixed overnight with 22C11-coated protein G-Sepharose in buffer C plus 2% BSA at 4°C on a shaker. After centrifugation, the precipitated beads were incubated with purified G₀ (1 μ g) in buffer C supplemented with 1.1 mM MgCl₂ and 2% BSA for 8-24 h at

10 4°C on a shaker. After washing four times with ice-cold buffer C, the centrifugation precipitate was subjected to SDS-PAGE, electroblotting, and immunodetection with the first antibodies (1 μ g/ml of 22C11; 10 μ g/ml of anti-Alz 90; 1/1000 dilution of 1C1; 1/500 dilution of 4G5; 0.1

15 μ g/ml of α GO1) and the second goat anti-mouse or anti-rabbit IgGs conjugated with HRP. (Immunodetection of 1C1 and 4G5, both of which are mouse IgM (κ), was accomplished using as second antibody a mixture of HRP-conjugated anti-rabbit IgG, rabbit anti-mouse IgM and

20 rabbit anti-mouse κ antibodies.) The three APP constructs prepared as described above are compared in the schematic diagram of Fig. 3b. The polypeptides encoded by all three constructs retain the entire transmembrane and extracellular domains of APP;

25 while Δ N (SEQ ID NO: 23) lacks all of the peptide 20 residues as well as the sequence on the carboxy terminal side of the peptide 20 region, Δ C (SEQ ID NO: 24) retains the peptide 20 sequence and is missing only the latter sequence.

30 Sf9 cells were infected, using standard methods, by recombinant baculoviruses encoding full length APP₆₉₅ cDNA (SEQ ID NO: 9), APP₁₋₆₅₆ cDNA (Δ N; SEQ ID NO: 23), or APP₁₋₆₇₆ cDNA (Δ C; SEQ ID NO: 24). In uninfected Sf9 cells, no immunoreactivity for anti-APP or anti-G₀

35 antibodies was detected (data not shown). The membranes

- 19 -

of Sf9 cells infected with the baculoviruses encoding APP₆₉₅ (SEQ ID NO: 9), ΔN (SEQ ID NO: 23), and ΔC (SEQ ID NO: 24) genes (referred to as Sf9-APP₆₉₅, Sf9-ΔN, and Sf9-ΔC, respectively) were found to express, respectively, 130-, 120- and 130-kDa proteins reactive with antibody 22C11 (Fig. 3d, right side). The Sf9-APP₆₉₅ cells expressed APP at $\approx 0.1\%$ of the total membrane protein. When the membranes of the three types of infected cells were immunoprecipitated with antibody Anti-Alz 90 (Boehringer Mannheim), a mouse monoclonal antibody specific for an epitope corresponding to residues 551-608 of APP (SEQ ID NO: 25; a section of APP that is within the extracellular domain), 130-kDa, 120-kDa, and 130-kDa proteins were recognized in Sf9-APP₆₉₅, Sf9-ΔN, and Sf9-ΔC cells, respectively (Fig. 3c, top panel). Membranes from all three types of infected cells showed approximately equivalent reactivity to the antibody, indicating that at least this portion of the extracellular domain was intact on each of the three and that all three cell types express approximately equal amounts of recombinant protein. When the antibody used was 1C1, a mouse monoclonal prepared against a peptide corresponding to residues 677-695 of APP (SEQ ID NO: 13), only Sf9-APP₆₉₅ membranes were reactive, indicating that the region corresponding to the C-terminal portion of the cytoplasmic domain is missing from both ΔN (SEQ ID NO: 23) and ΔC (SEQ ID NO: 24) (Fig. 3c, middle panel). When the antibody used was 4G5, a mouse monoclonal antibody raised against a peptide corresponding to residues 657-676 of APP (SEQ ID NO: 1; the peptide 20 region of the cytoplasmic domain), 130 kDa bands from both Sf9-APP₆₉₅ and Sf9-ΔC membranes reacted with the antibody, but Sf9-ΔN membranes did not, a demonstration that ΔN (SEQ ID NO: 23) but not ΔC (SEQ ID NO: 24) lacks the peptide 20 region of APP (Fig. 3c, bottom panel).

- 20 -

These experiments clearly indicate that the expressed proteins are recombinant APP₁₋₆₉₅ (SEQ ID NO: 9), APP₁₋₆₅₆ (SEQ ID NO: 23), and APP₁₋₆₇₆ (SEQ ID NO: 24), respectively, as designed.

5 The 22C11-precipitates from these Sf9 membranes expressing various forms of APP were exposed to purified G_o, reprecipitated with 22C11, and subjected to immunoblot analysis using anti-G_oα antibody αGO1 (Fig. 3d, left four lanes) and by 22C11 (right four
10 lanes). αGO1 (Morishita et al., Eur. J. Biochem. 174:87-94, 1988) was provided by Dr. Tomiko Asano; similar results were obtained when antibody GC/2 was substituted. The control lanes are 22C11-precipitate exposed to G_o in the absence of Sf9 membranes.
15 Approximately 1/10-1/20 (0.05-0.1 μg/tube) of the reconstituted G_o was precipitated, together with a comparable amount (≈0.1 μg/tube) of APP. Easily detectable amounts of G_oα were present in the final precipitate when G_o was mixed with 22C11-precipitates
20 from Sf9-ΔC or Sf9-APP₆₉₅ membranes, but essentially no G_oα was found in the final precipitate from Sf9-ΔN membranes. Thus, formation of an APP-G_o complex requires the peptide 20 region, residues 657-676 (SEQ ID NO: 1).

 In the experiment illustrated in Fig. 3e, 22C11-
25 precipitates from Sf9-APP₆₉₅ membranes (100 μg protein each) were incubated with activated G_o (lanes 2 and 4) or unactivated G_o (lanes 1 and 3); the final precipitates (left panel) and supernatants (right panel) were analyzed by simultaneous immunoblotting with 22C11 and αGO1
30 antibodies. Activation of G_o was carried out by incubating G_o in 20 mM Hepes/NaOH (pH 7.4), 1 mM EDTA, 2 mM MgCl₂, and 1 μM GTPγS overnight at room temperature. When G_o was incubated with GTPγS, no G_oα associated with the APP-22C11 complex (Fig. 3e), suggesting that the

- 21 -

activation state of the G protein regulates APP-G_o association.

This study suggests that APP functions as a receptor coupled to G_o through the G_o-activator cytoplasmic domain His⁶⁵⁷-Lys⁶⁷⁶ (SEQ ID NO: 1). APP has a point mutation in at least one form of familial Alzheimer's disease (Goate et al., Nature 349:704-706, 1991). A structural alteration of APP is therefore thought to be one cause of Alzheimer's disease, although it remains unknown how the mutation might produce the disease. One novel possibility suggested by this study is that the cytoplasmic, C-terminal fragment of APP is pathogenic. It has been suggested (Abraham et al., Biotechnology 7:147-153, 1989; Shivers et al., EMBO J. 7:1365-1370, 1988; Kametani et al., Biomedical Research 10:179-183, 1989) that the residual C-terminal portion of APP may remain in the cell membrane after abnormal cleavage of APP to produce β /A4 protein in Alzheimer's disease neurons. By analogy with the oncogenic transformation of c-erb B into v-erb B, such a structural alteration of APP may alter its function and prompt APP to constitutively activate G_o. This hypothesis is consistent with the study (Yanker et al., Science 245:417-420, 1989) indicating that recombinant expression of the C-terminal 105-residue portion of APP in neuronal cells evokes cell death, and with the reports that G_o activity is linked to neuronal growth cone motility (Strittmatter et al., BioEssays 13:127-134, 1990), axon and dendrite formation (Granneman et al., J. Neurochemistry 54:1995-2001, 1990), and memory (Guillen et al., EMBO J. 9:1449-1455, 1990). This study suggests that Alzheimer's disease is a disorder of an APP-G_o signalling system caused by structural alterations of APP.

- 22 -

Example 1

The screening method of the invention can be carried out as follows:

The assay used can be a very simple cell-free
5 assay employing a first polypeptide consisting essentially of the couplone, or G_o -binding portion, of APP (SEQ ID NO: 1) and a second polypeptide consisting essentially of an APP-binding portion of G_o . This APP-binding portion of G_o may be the 15-residue segment
10 identified as the anticouplone portion of G_o (SEQ ID NO: 3), or it may be one or both of the two flanking regions, residues 1-3 (SEQ ID NO: 4) and residues 19-36 (SEQ ID NO: 5) of G_o . Alternatively, longer portions, or all, of APP and/or G_o can be used, or the appropriate
15 portions of APP and/or G_o can be linked to other polypeptides to form hybrid polypeptides with characteristics (such as altered immunoreactivity or enzymatic activity) that would improve detection of the endpoint of the assay. The assay is carried out by
20 contacting the APP-based polypeptide with the G_o -based polypeptide in the presence of a candidate compound, in parallel with a control assay containing no candidate compound, and determining whether the candidate compound inhibits co-immunoprecipitation of the first and second
25 polypeptides (using either an antibody specific for the first polypeptide or an antibody specific for the second polypeptide). Alternatively, activation of the second (G_o) polypeptide may be the measured criterion: if so, the second polypeptide must include the GTP-binding
30 region of G_o (SEQ ID NO: 10), and GTP or an appropriate non-hydrolyzable analog thereof (such as GTP γ S or Gpp(NH)p) must be included in the assay. The assay may also be carried out using phospholipid vesicles prepared by standard methods (e.g., as described by Nishimoto et
35 al., J. Biol. Chem. 264:14029-14038, 1989), provided that

- 23 -

the first (APP) polypeptide includes a region of hydrophobic amino acids [such as all (SEQ ID NO: 8) or a portion (e.g., SEQ ID NO: 7) of the transmembrane region of APP) that permit it to be anchored in the phospholipid bilayer. Alternatively, the assay may be carried out using intact cells or red cell ghosts which contain APP and G_o , or appropriate portions thereof. The cells may express the first and second polypeptides naturally or by virtue of genetic engineering, or the polypeptides may be introduced directly into the cells or ghosts by standard means.

Example 2

The progress of Alzheimer's disease may be halted or reversed by treating a patient with a compound which diminishes the activation of neural G_o by truncated APP. Such a compound may be identified in a screening assay as described above, or may consist essentially of a polypeptide containing the amino acid sequence of (a) the couplone region of APP (SEQ ID NO: 1), (b) the anticouplone region of G_o (SEQ ID NO: 3), or (c) the APP-associating region(s) of G_o (SEQ ID NO: 4 and/or 5), or a combination of (b) and (c). Such polypeptides may be produced in quantity by standard recombinant means, or by standard synthetic techniques. To minimize proteolytic degradation *in vivo*, the carboxy and amino termini may be derivatized (e.g., with ester or amide groups), some or all of the amino acids may be replaced with D-amino acids, or particularly sensitive peptide linkages may be substituted with non-peptide bonds using standard methodology. To improve penetration of the blood-brain barrier (BBB), the polypeptides may be altered to increase lipophilicity (e.g., by esterification to a bulky lipophilic moiety such as cholesteryl) or to supply a cleavable "targetor" moiety that enhances retention on

- 24 -

the brain side of the barrier (Bodor et al., Science 257:1698-1700, 1992). Alternatively, the polypeptide may be linked to an antibody to the transferrin receptor, in order to exploit that receptor's role in transporting
5 iron across the blood-brain barrier, as taught by Friden et al., Science 259:373-377, 1993. It is expected that an intravenous dosage equivalent to approximately 1 to 100 μ moles of the polypeptide of the invention per kg per day, or an intrathecally administered dosage of
10 approximately 0.1 to 50 μ moles per kg per day, will be effective in blocking activation of G_o in an Alzheimer's patient. If the polypeptide is sufficiently protected from proteolytic degradation, as described above, it may also be administered orally in appropriately higher
15 doses. Alternatively, the compound may be incorporated into a slow-release implant to ensure a relatively constant supply of the therapeutic to the patient's brain.

CLAIMS

1. A method of identifying a therapeutic useful for treating or preventing the symptoms of Alzheimer's disease, which method includes the steps of

5 contacting (a) a first molecule comprising the couplone portion (SEQ ID NO: 1) of amyloid precursor protein (APP) with (b) a second molecule comprising an APP-associating region of G_o (SEQ ID NOS: 3, 4, or 5), in the presence of a candidate compound; and

10 determining whether said candidate compound interferes with the association of said first and second molecules, said interference being an indication that said candidate compound is a therapeutic useful for treating Alzheimer's disease.

15 2. The method of claim 1, wherein said determining step is accomplished by immunoprecipitating said first molecule with an antibody specific for APP; and

20 detecting the presence or amount of said second molecule which co-precipitates with said first molecule.

3. The method of claim 1, wherein said determining step is accomplished by immunoprecipitating said second molecule with an antibody specific for G_o; and

25 detecting the presence or amount of said first molecule which co-precipitates with said second molecule.

4. The method of claim 1, wherein said first molecule comprises the portion of APP₆₉₅ from residues 649 to 695 (SEQ ID NO: 6).

- 48 -

5. The method of claim 1, wherein said first molecule comprises the portion of APP₆₉₅ from residues 639 to 648 (SEQ ID NO: 7).

6. The method of claim 1, wherein said first molecule comprises the portion of APP₆₉₅ from residues 640 to 695 (SEQ ID NO: 26).

7. The method of claim 6, wherein said first molecule comprises essentially all of APP₆₉₅ (SEQ ID NO: 27).

8. The method of claim 1, wherein said second molecule comprises the GTP-binding region of G_o (SEQ ID NO: 10).

9. The method of claim 8, wherein said second molecule comprises essentially all of G_o (SEQ ID NO: 2).

10. A method of assaying for a therapeutic useful for treating Alzheimer's disease, which method includes the steps of

contacting (a) a first molecule comprising the couplone region of APP (SEQ ID NO: 1) with (b) a second molecule comprising an APP-associating region of G_o (SEQ ID NO: 3, 4, or 5), in the presence of a candidate compound; and

determining whether said candidate compound interferes with the activation of said second molecule by said first molecule, said interference being an indication that said candidate compound is a therapeutic useful for treating Alzheimer's disease.

11. The method of claim 10, wherein said determining step is accomplished by

- 49 -

contacting said second molecule with a substrate comprising GTP or an analog of GTP; and

detecting or measuring the binding of said substrate to said second molecule, wherein said binding
5 is evidence of said activation of said second molecule by said first molecule.

12. The method of claim 1, wherein said contacting step is carried out at a Mg^{2+} concentration between 1×10^{-7} and 1×10^{-2} M.

10 13. The method of claim 10, wherein said contacting step is carried out at a Mg^{2+} concentration between 1×10^{-7} and 1×10^{-2} M.

14. The method of claim 1, wherein said contacting step is carried out in a cell-free system.

15 15. The method of claim 10, wherein said contacting step is carried out in a cell-free system.

16. A system for screening candidate Alzheimer's disease therapeutics, which system comprises
a first polypeptide comprising a sequence
20 essentially identical to that of peptide 20 (SEQ ID NO: 1);

a second polypeptide comprising a sequence essentially identical to the anticouplone sequence of G_o (SEQ ID NO: 3); and

25 a means for detecting either (a) the association of said first polypeptide with said second polypeptide, or (b) the activation of said second polypeptide by said first polypeptide.

- 50 -

17. A cell-free system for screening candidate Alzheimer's disease therapeutics, which system comprises
a first polypeptide comprising a sequence
essentially identical to that of peptide 20 (SEQ ID
5 NO: 1); and

a second polypeptide comprising a sequence
essentially identical to the anticouplone sequence of G_o
(SEQ ID NO: 3).

18. The system of claim 17, wherein said first
10 polypeptide is anchored to a solid material or is in a
phospholipid vesicle.

19. The system of claim 17, wherein said second
polypeptide further comprises residues 1 to 3 (SEQ ID
NO: 4) and 19 to 36 (SEQ ID NO: 5) of G_o .

15 20. The system of claim 19, wherein said second
polypeptide comprises G_{o1} or G_{o2} .

21. A method for diminishing the activation of G_o
in a neuronal cell by treating the cell with a compound
which blocks association of G_o with the cytoplasmic tail
20 of APP.

22. The method of claim 21, wherein the compound
is a peptide fragment of G_o or of the cytoplasmic tail of
APP.

23. The method of claim 21, wherein said cell is
25 within an animal.

24. The method of claim 23, wherein said animal
is a human.

- 51 -

25. A method for preventing or treating Alzheimer's disease in a patient, comprising treating the patient with a compound which blocks association of G_o with the cytoplasmic tail of APP.

5 26. A method for preventing or treating Alzheimer's disease in a patient, comprising treating the patient with a compound which inhibits activation of neuronal G_o by the cytoplasmic tail of APP.

10 27. A peptide having less than 50 amino acids and comprising the sequence of peptide 20 (SEQ ID NO: 1).

28. A therapeutic composition comprising the peptide of claim 27 and a pharmaceutically acceptable carrier.

15 29. A method for identifying a ligand for which APP is a receptor, which method includes the steps of providing an APP molecule and a G_o molecule; contacting a candidate compound with the extracellular domain of said APP molecule, the cytoplasmic tail of said APP molecule being accessible to
20 said G_o molecule, and

detecting either (a) association of said G_o molecule with said APP molecule, or (b) activation of said G_o molecule by said APP molecule, said association or activation being evidence that said candidate compound
25 is a ligand of APP.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US94/01712**Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)**

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

- I. Claims 1-20, 27-29, drawn to a composition and a method of use, Class 436, Subclass 518, and Class 530, subclass 350.
- II. Claims 21-26, drawn to a treatment method, Class 512, Subclass 12.

Groups I and II do not share a common special technical feature as represented in PCT Rule 13.2 because they are drawn to completely different methods requiring different process steps for completion. Note that PCT Rule 13.2 does not provide for multiple methods within a single inventive concept.

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
1-20, 27-29

Remark on Protest

☐

The additional search fees were accompanied by the applicant's protest.

☐

No protest accompanied the payment of additional search fees.

Lipopolysaccharide-Binding and Neutralizing Peptides

The present invention relates to substances which bind with high affinity to endotoxin (lipopolysaccharide [LPS]), and which are useful for the prevention or treatment of a variety of conditions and diseases, such as of Gram-negative and Gram-positive bacterial sepsis, or bacterial or fungal infections. Furthermore, said substances may be used for neutralizing effects associated with heparin. The substances are LPS-binding peptides comprising an LPS-binding domain. The invention also encompasses methods for the detection and removal of bacterial LPS from solutions.

In humans, LPS released during infection by Gram-negative bacteria can cause the severe pathological changes associated with septic shock (Duma, *Am. J. Med.* 78 (1985) 154-163; Glauser et al., *Lancet* 338 (1991), 732-736). In the United States, septic shock is responsible for between 100,000 and 300,000 deaths annually (Ziegler et al., *N. Eng. J. Med.* 324 (1991), 429-436) and in Germany for between 70,000 and 100,000. Although a variety of agents have been evaluated for neutralizing LPS or enhancing its clearance *in vivo*, there remains no specific treatment for Gram-negative bacterial sepsis.

LPS is a glycolipid that is ubiquitous in the outer membrane of Gram-negative bacteria (Raetz, *Annu. Rev. Biochem.* 59 (1990), 129-170). LPS consists of an oligosaccharide and a lipid portion and is characterized by an overall negative charge, stability to heat, and high molecular weight. While the chemical structure of most LPS molecules is complex and diverse, a common feature is the lipid A region. Lipid A, the membrane anchor of LPS, consists of a central phosphodisaccharide unit that is attached to up to seven fatty acid chains. Most of the biological activities of LPS reside in the lipid A portion (Galanos et al., *Eur. J. Biochem.* 145, (1985), 1-5).

Septic shock is a complex condition which arises from a cascade of molecular and cellular events following infection by microorganisms, predominant among which are Gram-negative bacteria. The onset of shock arises from the interaction of LPS or lipid A with membrane-bound receptors on macrophages and blood monocytes (Couturier et al., *J. Immun.* 147 (1991), 1899-1904) or various serum proteins, such as the septins (Wright et al., *J. Exp. Med.* 176 (1992), 719-727). These interactions lead to an increase in the levels of pro-inflammatory mediators such as tumor necrosis factor, IL-1, IL-6, and interferon- γ . Endothelial cells are also stimulated to produce factors which attract neutrophils. Release of enzymes and other factors by activated neutrophils causes damage to local vasculature which can lead rapidly to death.

One approach to the treatment of sepsis is the use of substances which bind to LPS and neutralize its toxic effects *in vivo*. Although there are numerous proteins which bind LPS, the number of substances which effectively neutralize LPS *in vivo* are very few. A number of such substances have been identified, including polymyxins (Morrison et al., *Immunochem.* 13 (1976), 813-818), polymyxin-derived peptides (Rustici et al., *Science* 259 (1993), 361-365), polyclonal (Ziegler et al., *N. Eng. J. Med.* 307 (1982), 1225-1230) and monoclonal (Ziegler et al. (1991), *loc. cit.*) antibodies, bactericidal/permeability-increasing protein (BPI) (Marra et al., *J. Immun.* 148 (1992), 532-537), lipopolysaccharide binding protein (LBP) (Schuhmann et al., *Science* 249 (1990), 1429-1431), and Limulus anti-LPS factor (LALF) (Akategawa et al., *J. Biol. Chem.* 261 (1986), 7357-7365, Muta et al., *J. Biochem.* 101 (1987), 1321-1330).

The simplest molecules that bind to the lipid A portion of LPS with high affinity are the polymyxin antibiotics; these are positively charged amphipathic cyclic oligopeptides attached to a lipid tail. Although polymyxins bind to

LPS/lipid A with high affinity, they suffer the drawback from a therapeutic stand-point of having unacceptably high toxicity (Craig et al., *Infect. Immun.* 10 (1974), 287-292). The LPS-binding monoclonal antibodies HA-1A and E5 both failed to demonstrate positive clinical effects for the treatment of Gram-negative septic shock. One of the main problems associated with these antibodies is non-specificity; for example, HA-1A binds tightly to numerous hydrophobic structures apart from lipid A (see, for example, Baumgartner et al., *J. Exp. Med.* 171 (1990), 889-896). The human proteins BPI and LBP are both being investigated for the treatment of Gram-negative sepsis (Marra et al., loc. cit.; Ulevitch et al. (1986), WP 86/06279). BPI, which is stored in specific granules of polymorphonuclear cells, kills Gram-negative bacteria by binding to membrane-bound LPS and disrupting the permeability barrier. LBP is a mammalian serum protein which also binds very tightly to LPS. Although LBP shares sequence homology with BPI (Schuhmann et al., loc. cit.), it is not directly cytotoxic to Gram-negative bacteria and its precise function is obscure. Most recently, LALF has been investigated for use in sepsis (Warren et al., *Infect. Immun.* 60 (1992), 2506-2513; Wainwright et al. (1992) WO 92/20715). This protein is almost certain to suffer the disadvantages associated with other foreign proteins for human therapy; it is immunogenic and has only a short half-life in circulation. These factors will reduce its clinical potential. None of these substances have been proven to be effective for the treatment of the serious conditions associated with Gram-negative infection.

Thus, the technical problem underlying the present invention is to provide substances which bind LPS released by Gram-negative bacteria, neutralize its toxic effects, and exhibit no toxicity.

The solution to the above technical problem was achieved by providing substances which relate to peptides which bind

tightly to LPS, and therefore have utility in the diagnosis and treatment of Gram-negative and other septic conditions.

Thus, the present invention relates to LPS-binding peptides comprising an LPS-binding domain comprising at least:

(a) the amino acid sequence 1-2-3-4-5-6-7-8, wherein the numbers represent any of the following amino acids:

- 1 = a polar or positively charged amino acid, preferably
C, H, K, N, Q, R, S, T, W, or Y;
- 2 = a hydrophobic amino acid, preferably
A, F, H, I, L, M, V, or W;
- 3 = a basic amino acid, preferably H, K, or R;
- 4 = a hydrophobic or positively charged amino acid, preferably
A, F, H, I, K, L, M, R, V, or W;
- 5 = a hydrophobic, polar, or positively charged amino acid, preferably
A, C, F, H, I, K, L, M, N, Q, R, S, T, V, W, or Y;
- 6 = a positively charged amino acid, preferably K or R;
- 7 = A hydrophobic, polar, or positively charged amino acid, preferably
A, C, F, H, I, K, L, M, N, Q, R, S, T, V, W, or Y;
- 8 = a hydrophobic or positively charged amino acid, preferably
A, F, H, I, K, L, M, R, V, or W;

(b) a corresponding inverse amino acid sequence; or

(c) a variation of said amino acid sequence (a) or (b) capable of effectively binding to LPS.

The peptides of the present invention effectively bind to LPS, i.e. they interact specifically with LPS with an association constant greater than 10^5 M^{-1} . In this context, an LPS-binding peptide is a chain of amino acids linked to each other by peptide bonds. An LPS-binding domain is the

shortest possible chain of amino acids within an LPS-binding peptide which effectively binds to LPS.

All peptide structures disclosed use the single letter code for amino acids.

The figures show:

Figure 1: A schematic diagram of the LALF loop indicating the direction of side-chains and the putative locations of the corresponding residues in LBP and BPI. The three letters at each position correspond to the amino acid residues in LALF, LBP and BPI, respectively. Solid bonds/dashed bonds indicate side chains pointing out of/into the plane of the diagram.

Figure 2 shows the peptides which are used to define a minimum LPS-binding domain in LALF. The two cysteine residues are linked by a disulphide bond.

Figure 3 shows the peptides which are used to define a minimum LPS-binding domain in LBP. The two cysteine residues are linked by a disulphide bond.

Figure 4 shows the peptides which are used to define the LPS-binding domain in BPI. The two cysteine residues are linked by a disulphide bond.

Figure 5 shows the aligned sequences of LALF, LBP and BPI in which the LBP and the BPI sequences are listed from the C-terminus to the N-terminus while the LALF sequence is written from the N-terminus to the C-terminus.

Figure 6 shows the peptides which are used to define the LPS-binding activity in the inverse orientation. The two cysteine residues are linked by a disulphide bond.

Figure 7 shows a list of the peptides in which point mutations are introduced into peptides resembling the minimal LPS binding domain of LBP. The two cysteine residues are linked by a disulphide bond.

Figure 8 shows ELISA data for the binding of LALF-derived peptides to lipid A. The four biotinylated peptides are allowed to bind to immobilized lipid A, and bound peptide is detected using a streptavidin-alkaline phosphatase conjugate. For more details, see Example 1.

Figure 9 shows ELISA lipid A binding data for peptides derived from LBP, BPI, and the generalized motif described here in comparison with the LALF-derived peptide. The biotinylated peptides are allowed to bind to immobilized lipid A, and bound peptide is detected using a streptavidin-alkaline phosphatase conjugate. For more details, see Example 1.

Figure 10 shows ELISA data for the binding of the LALF-derived peptide LALF-14 to different types of lipopolysaccharide. The biotinylated peptide is allowed to bind to immobilized lipid A or LPS, and bound peptide is detected using a streptavidin-alkaline phosphatase conjugate. For more details, see Example 2.

Figure 11 shows the ELISA data which reveals the difference between cyclic and linear peptides in binding to lipid A. The biotinylated peptides are allowed to bind to immobilized lipid A, and bound peptide is detected using a streptavidin-alkaline phosphatase conjugate. For more details, see Example 3.

Figure 12 shows ELISA data for the binding of fluorescein-labelled LPS to biotinylated peptides derived from LALF, LBP, BPI and the generalized motif described here, which are

immobilized on the ELISA plate through interaction with streptavidin. For more details, see Example 4.

Figure 13 shows ELISA data for the competition between LALF and LALF-derived peptides for binding to lipid A. Increasing concentrations of peptide are allowed to compete with a fixed concentration of LALF for binding to immobilized lipid A. Bound LALF is detected using an anti-rabbit antibody conjugated to alkaline phosphatase. For more details, see Example 5.

Figure 14 shows ELISA data for the competition between LALF and various peptides for binding to immobilized lipid A at a single peptide concentration. The extent to which the peptide inhibits LALF binding (measured via an anti-rabbit antibody) to lipid A is determined at 100 $\mu\text{g/ml}$ of peptide. For more details, see Example 5.

Figure 15 shows ELISA data for the competition between LBP and various peptides for binding to immobilized lipid A at a single peptide concentration. The extent to which the peptide inhibits LBP binding (measured via an anti-rabbit antibody) to lipid A is determined at 100 $\mu\text{g/ml}$ of peptide. For more details, see Example 6.

Figure 16 shows ELISA data for the competition between the peptide LBP-14 and various peptides and proteins for binding to immobilized lipid A at a single peptide concentration. The extent to which the biotinylated LBP-14 inhibits peptide or protein binding (measured using a streptavidin-alkaline phosphatase conjugate) to lipid A is determined at 1 $\mu\text{g/ml}$ and 100 $\mu\text{g/ml}$ of peptide. For more details, see Example 7.

Figure 17 shows ELISA data which illustrates the effect of increasing concentrations of serum on the binding of peptides to immobilized lipid A. Biotinylated peptides are detected

using a streptavidin-alkaline phosphatase conjugate. For more details, see Example 8.

Figure 18 shows ELISA data which illustrates the effect of increasing concentrations of serum on the ability of peptides to compete with LALF for binding to immobilized lipid A. The extent to which the peptide inhibits LALF binding (measured via an anti-rabbit antibody) to lipid A is determined at 100 $\mu\text{g/ml}$ of peptide of 0% and 10% fetal calf serum. For more details, see Example 9.

Figure 19 shows data for the inhibition by peptides of the Limulus amebocyte lysate gelling and chromogenic assays. The peptides are tested either for their ability to inhibit LPS-mediated gelling of Limulus amebocyte lysates or to inhibit the LPS-colour reaction in the chromogenic Limulus amebocyte lysate assay. For more details, see Example 10.

Figure 20 shows data for the inhibition, by a fixed concentration of four different peptides, of the LPS-mediated release of tumour necrosis factor by monocytes. TNF is detected using a commercial ELISA kit. For more details, see Example 11.

It has surprisingly been found by the inventors that the crystal structure of LALF reveals a novel but simple tertiary fold which has a striking shape and amphipathicity. A surface-extended loop in the LALF structure (loop of LALF or LALF-loop) has similar features to polymyxin B by being positively charged and amphipathic and having several exposed hydrophobic and aromatic residues. Furthermore, the loop of LALF is distinguished by an alternating series of positively charged and hydrophobic/aromatic residues that, by virtue of the extended β -conformation, point in opposite directions, and a single pair of positive charges, that, because of the β -turn conformation, point in the same direction and maintain

the amphipathicity. The loop contains no negatively charged amino acids.

A similar amphipathic loop exists in three other proteins which bind LPS: rabbit and human lipopolysaccharide-binding protein (LBP) and human bactericidal/permeability-increasing protein (BPI) (Figure 1). Inspection of the LBP and BPI sequences reveals a similar pattern of alternating residues that could produce an amphipathic loop; the 19 residue stretch contains six basic and no acidic amino acids. Near the top of the loop, one amphipathic pair of residues (Ser/Arg96 and Phe97) is reversed, but it is possible that a different conformation of the hairpin turn would maintain the amphipathicity of the loop in BPI and LBP.

The deduced sequence and structural homology within this set of LPS-binding proteins led to the design of the peptides which are the subject of the present invention. All of the LPS-binding peptides encompassed by the present invention can be prepared using standard methods of peptide synthesis, as described by, for example, S.D.H. Kent (*Ann. Rev. Biochem.* 57, (1988), 957), which is apparent to anyone skilled in the art. Alternatively, the peptides can be synthesized biologically using a recombinant microorganism which has been genetically engineered to contain DNA sequences encoding the peptides (Sambrook et al., *Molecular Cloning, A Laboratory Manual*, CSH Press (1989)).

In another embodiment, the present invention relates to peptides having an inverse amino acid sequence derived from an LPS-binding peptide and also effectively binding to LPS. Thus, the present invention also encompasses such peptides. In this context, an inverse amino acid sequence is a chain of amino acids which, when read from the N-terminus to the C-terminus, has the same sequence as the parent peptide when read from the C-terminus to the N-terminus. There exists homology between LBP/BPI sequences from amino acids 90 to 97 and the LALF sequence from residues 38 to 45 when the LBP/BPI sequence is read from the C-terminus to the N-terminus

(Figure 5). On this basis, "inverse" peptides were synthesized and tested for their ability to bind LPS. Particularly preferred are the inverse peptides shown in Figure 6 which effectively bind to LPS, as shown by ELISA.

In still another embodiment, the present invention relates to peptides which share a common structural motif with the above peptides and are also able to bind LPS. Thus, the present invention also provides for an LPS-binding peptide comprising an LPS-binding domain in which the amino acid sequence includes a variation. In this context, a variation of an amino acid sequence refers to any changes in the sequence that are introduced either by an insertion or a deletion of one or more amino acids. Particularly preferred are the peptides shown in Figure 7, in which mutations have been introduced in the parent peptide structure. These altered peptides both bind to LPS, as shown by ELISA.

In a preferred embodiment, the present invention provides LPS-binding peptides, wherein the amino acid sequence (a) is any combination of the amino acids seen in the LPS-binding loops of LALF, LBP, or BPI, namely:

- 1 = T or R or K
- 2 = F or W
- 3 = R or K
- 4 = R or V or A
- 5 = L or R or Q
- 6 = K
- 7 = W or S or R
- 8 = K or F

In a further preferred embodiment, the present invention provides peptides of the general motif outlined above, with the additional feature that the N-terminus is extended by two or more amino acids denoted -2 and -1, in which amino acid -2, which is the new N-terminus, is taken from the set R, K, H, N and Q, and amino acid -1 is any amino acid.

In a further preferred embodiment, the present invention provides peptides of the general motif outlined above with the additional feature that the C-terminus is extended by addition of cysteine, and the N-terminus is extended by two or more amino acids denoted -2 and -1 in which the amino acid -2, which is the new N-terminus, is taken from the set R, K, H, N and Q, and amino acid -1 is cysteine, the two cysteines being linked by a disulphide bond.

In a more preferred embodiment, the LPS-binding peptides have the amino acid sequence TFRRLKWK, RWKVRKSFFKLQ, or KWKAQKRFLKMS.

In a further preferred embodiment, the present invention provides linear peptides which are able to bind LPS effectively. Particularly preferred are peptides derived from LALF. Disulfide-constrained circular peptides (see below) spanning amino acids 31 to 52 and amino acids 38 to 45 of LALF are incubated with DTT to reduce the disulfide bond. The peptide spanning amino acids 31 to 52 binds effectively to lipid A as determined by ELISA. The peptide spanning residues 38 to 45 interacts only weakly with lipid A, as determined by ELISA.

In a still further preferred embodiment, the present invention provides for peptides which effectively bind to LPS and are constrained to adopt a circular conformation by an intramolecular bridge. In this context, the circular conformation can be brought about by any one of a number of intramolecular bridges. Preferably, the peptide may incorporate two cysteine residues between which a disulfide bond is formed by an oxidation reaction. Alternatively, the two cysteines may be linked through a homo-bifunctional cross-linking reagent, such as a bis-maleimide.

Particularly preferred are the cyclic peptides comprising amino acids 31 to 52 and amino acids 38 to 45 of LALF, each stabilized by a disulfide bond formed between two cysteine

residues, producing a cyclic conformation (Figure 2). Both bind lipid A and, additionally, two different types of LPS-molecules, *E. coli* J5-LPS and *E. coli* EH 100 LPS, as determined by ELISA. This defines a minimal LPS-binding domain to be the peptide spanning amino acids 38 to 45 of LALF.

Peptides derived from LBP according to the alignment as shown in Figure 1, which are constrained to adopt a cyclic conformation by means of a disulfide bond formed between two unique cysteine residues, are also able to bind LPS, as shown by ELISA. Thus, particularly preferred are also the peptides spanning amino acids 90 to 101 and amino acids 90 to 97 of LBP (Figure 3). Conversely, the peptide spanning amino acids 92 to 99 of LBP does not bind LPS. This defines a second minimal LPS binding domain to be the peptide spanning amino acids 90 to 97 of LBP. Furthermore, the fact that the peptide ranging from amino acids 92 to 99 does not bind lipid A although it is positively charged and amphipathic indicates that these features alone are not sufficient to provide an LPS-binding motif, further illustrating the novelty of the present invention.

Peptides derived from BPI according to the alignment shown in Figure 1, which are constrained to adopt a cyclic conformation by means of a disulfide bond between two unique cysteine residues, are also able to bind LPS as shown by ELISA. Particularly preferred are the peptides spanning amino acids 90 to 97 and amino acids 90 to 101 of BPI (Figure 4). This defines a third minimal LPS-binding domain to be the peptide spanning amino acids 90 to 97 of BPI.

In a further preferred embodiment, the present invention provides a detectably-labeled peptide which can be used in an assay for the determination of LPS in a biological sample. In this context, a detectably-labeled peptide is a peptide which is covalently linked to a substance which can readily be detected. Most commonly, the label is an enzyme, fluorescent substance, or radionuclide. By way of example, the peptide

may be linked to an enzyme such as β -galactosidase, peroxidase, or alkaline phosphatase, which, in the presence of an appropriate substrate, can lead to the generation of a colored or fluorescent product which is readily detected. Alternatively, the peptide may be linked directly to a fluorescent substrate, such as fluorescein, rhodamine, or auramine for the purposes of detection. Commonly used labelling radionuclides include ^{14}C , ^{131}I , ^3H , ^{125}I , and ^{35}S . Many variations on labelling configurations can be imagined. For example, the peptide may be linked through an intermediary substance, such as biotin, to another substance, such as streptavidin, which is itself linked to a substance which enables detection according to conventional methods.

In a preferred embodiment, the present invention provides a set of LPS-binding peptides each comprising one or more LPS-binding domains.

The present invention also includes DNA sequences encoding the peptides of the present invention, as well as vectors, such as plasmids, phagemids, and cosmids containing these DNA sequences.

Additionally, the present invention encompasses microorganisms such as viruses, bacteria and yeast which have been transformed with these vectors. The DNA sequences provided herein are most readily obtained using standard methods of automated DNA synthesis, but can also be obtained by conventional molecular cloning. For example, those DNA sequences derived from the naturally-occurring proteins LBP, BPI, or LALF can be obtained in a form suitable for cloning by use of the polymerase chain reaction, as will be apparent to anyone skilled in the art (Sambrook et al., loc. cit.).

Furthermore, the present invention relates to a method for the production of an LPS-binding peptide according to the invention, comprising culturing a microorganism transformed

with a recombinant vector comprising a DNA encoding the peptide of the invention, and recovering said peptide or a fusion protein containing it from the medium.

In a preferred embodiment, the present invention provides a pharmaceutical composition comprising effective amounts of any of the peptides described above in combination with a pharmaceutically acceptable carrier and/or diluent. The pharmaceutical composition can be used for the treatment of a variety of conditions related to the release of LPS, especially Gram-negative sepsis. In this context, the term sepsis refers to the morbid conditions induced by a toxin, the introduction or accumulation of which is most commonly caused by infection or trauma. The initial symptoms of sepsis typically include chills, profuse sweat, irregularly remittent fever, prostration and the like, followed by persistent fever, hypotension leading to shock, neutropenia, leukopenia, disseminated intravascular coagulation, adult respiratory distress syndrome and multiple organ failure.

The peptides which are the subject of the present invention are similar in structure to a number of peptides which derive from BPI, which have been the subject of investigation for their therapeutic properties (see, for example, Little et al., *J. Biol. Chem.* 269 (1994) 1865-1872). In addition to their endotoxin binding and neutralization capabilities by comparison with the BPI-derived peptides, the peptides which are described here may be expected to show bactericidal and heparin binding activity. Accordingly, the present invention furthermore provides pharmaceutical compositions which can be used to kill bacteria (both Gram-negative and Gram-positive) and fungi as well as pharmaceutical compositions which possess the ability to neutralize properties associated with heparin, such as anticoagulation, angiogenesis, and growth factor-induced tumour and endothelial cell proliferation.

In a further preferred embodiment, the present invention also encompasses a diagnostic kit. Such a kit would comprise at least a peptide or a labelled peptide as set out above and would consist additionally of the reagents and materials necessary to carry out a standard competition or sandwich assay. Said diagnostic kit can be used for the determination of LPS or for the diagnosis of septic conditions.

In a still further preferred embodiment, the present invention provides the peptides disclosed herein immobilized on a solid support. Most conveniently, the peptide is covalently linked to a solid support such as cellulose, agarose, polyacrylamide, etc, which is modified so as to bear a reactive functionality such as an imidate, activated ester, activated disulfide, epoxide, etc. The peptide can be linked by any one of a number of methods which are commonly used in protein chemistry. By way of example, an N-terminal or C-terminal cysteine can readily be introduced into the peptide during synthesis. The thiol function of this cysteine residue can be used to link the peptide to a solid support which has been derivatized to bear a maleimide group. The present invention also provides a method of removing LPS from solutions, whereby said solution is passed over the immobilized peptides of the invention. This method is of particular interest in the purification of pharmaceutical preparations, LPS contamination of which is a frequently-occurring problem.

Now that the invention has been generally described, it will be illustrated by the following specific examples, which are provided for the purpose of illustration only and are not intended to limit the scope of the invention.

Example 1: Binding of peptides to lipid A

Peptides are synthesized using standard Fmoc chemistry on an ABIMED AMS 422 synthesizer. The cleaved peptides are oxidized

overnight in DMSO at room temperature, purified on a C-18 reversed phase column with a gradient of acetonitrile/0.1% trifluoroacetic acid, and characterized by mass spectroscopy.

To confirm the hypothesis that the loop sequence of LALF binds lipid A and LPS, peptides comprising parts of the LALF loop are synthesized, ranging in length from 8 to 12 amino acids. The peptides comprising amino acids 36 to 47 (LALF-14), and amino acids 38 to 45 (LALF-10) of LALF, are stabilized by a disulfide bond through the introduction of cysteine residues at the N- and C- termini of the peptides, thus adopting a cyclic conformation. The peptide comprising amino acids 36 to 45 (LALF-11), in which amino acid 37 is replaced by a cysteine is also cyclized following introduction of a second cysteine residue at the C-terminus of the peptide. All peptides are labelled at the N-terminus with biotin.

The lipid A-binding activities of the peptides are shown in an ELISA format as follows. An ELISA plate (NUNC, Polysorp 96U) is coated for 90 minutes at 37°C with 100 μ l lipid A in PBS (0.25-1 μ g/ml). All further steps are done at room temperature. After washing and blocking (10 min.) with PBS/0.1% Tween, the solid phase is incubated for 1 hour with 100 μ l of increasing amounts (0.1 μ g/ml - 10 μ g/ml) of purified synthetic peptides (dissolved in PBST) labelled at the N-terminus with biotin. After washing with PBS/0.1% Tween, the bound peptides are incubated for 45 min. with 100 μ l streptavidin conjugated to alkaline phosphatase (Boehringer Mannheim GmbH; 1:10000 diluted in PBS/0.1% Tween), followed again by washing with PBS/0.1% Tween and 100mM Tris pH 9.5. p-Nitrophenylphosphate (2 mg/ml in 100mM Tris pH 9.5) is used as a substrate for alkaline phosphatase. The ELISA is read at 405nm.

Increasing amounts of peptide are added to immobilized lipid A. LALF-14, LALF-11 and LALF-10 bind lipid A with high

activity (see Figure 8). The cyclic peptide comprising the inverted sequence from amino acids 38-45, RETL-10, binds lipid A only slightly above background level, which is set by the control peptide. This result indicates that, although RETL-10 is positively charged and amphipathic, these features alone are not sufficient to provide high affinity LPS-binding, illustrating the novelty of the present invention.

The peptides derived from LBP comprising amino acids 90 to 101 (LBP-14), amino acids 92 to 99 (LBP-10-1) and amino acids 90 to 97 (LBP-10-2), the peptide derived from BPI comprising amino acids 90 to 101 (BPI-14), and two peptides comprising an amino acid sequence randomly chosen from the motif defined herein (MS-21 (Biotin-Z-K-C-F-T-R-R-A-K-W-R-C (Z = β -alanine)), MS-22 (Biotin-Z-C-K-W-K-I-R-K-F-S-C-N (Z = β -alanine))) are stabilized by formation of a disulfide bond formed by the oxidation of cysteines introduced at the N- and C- termini of the peptides, giving cyclic peptides. Each is labelled at the N-terminus with biotin.

The lipid A-binding activity of the peptides is tested in an ELISA format as described above, in which increasing amounts of peptide is added to immobilized lipid A (see Figure 9). LALF-14 is used as a control for high activity binding and the irrelevant peptide Nor (G-A-T-P-E-D-L-N-T-L) to determine background binding. Of the new peptides based on LBP, LBP-14 binds lipid A as well as LALF-14, LBP-10-1 only in its highest concentration (10 μ g/ml) binds lipid A above background, while LBP-10-2 binds lipid A only slightly above background. The peptide based on BPI, BPI-14, binds lipid A above background, but significantly weaker than LALF-14 and LBP-14. Of the peptides based on the LPS binding motif, MS-21 and MS-22, MS-21 binds lipid A weaker than LALF-14 and LBP-14, but slightly better than BPI-14. MS-22 binds lipid A clearly above background level and with a similar activity to LBP-10-1, but weaker than MS-21.

Example 2: Binding of LALF-14 to lipid A and LPS

The cyclic peptide comprising amino acids 36 to 47 of LALF (LALF-14) is tested for binding different kinds of lipopolysaccharides in comparison with lipid A. in an ELISA format in which increasing amounts of peptide are added to immobilized lipid A and LPS. The forms of lipopolysaccharide used are E.coli Re F515; Klebsiella p.; Salmonella e.; Shigella f.; and E.coli 0127:B8. LALF-14 is able to bind to all species of lipopolysaccharide above background, but with different activities (see Figure 10). Thus, LALF-14 binds Salmonella e. as well as it binds to lipid A, E.coli Re F515 and Shigella f. with less activity than lipid A but with higher activity than Klebsiella p. and E.coli 0127:B8.

Example 3: Importance of conformation for peptide-lipid A binding

To investigate the importance of the constrained conformation for high affinity peptide-lipid A binding, binding activity of cyclic and the corresponding linear peptides is compared. This is achieved (i) by reducing peptides LALF-14, LBP-14 and BPI-14 with DTT to destroy the disulphide bond and (ii) by synthesizing a linear peptide comprising amino acids 36 to 45 (LL-10) for comparison with LALF-11. The lipid A-binding activity of the peptides is tested in an ELISA format (*vide infra*) in which increasing amounts of peptide are added to immobilized lipid A. In all cases, the oxidized peptides LALF-14, LBP-14 and BPI-14 display higher lipid A binding activity compared with the reduced peptides, LALF-14/DTT, LBP-14/DTT and BPI-14/DTT, demonstrating that a constrained cyclic form is superior to a linear conformation for high lipid A binding activity (see Figure 11). This result is confirmed by the observation that the lipid A binding activity of the cyclic peptide LALF-11 is higher than that of its linear counterpart LL-10.

Example 4: Binding of fluorescein-labelled LPS to biotinylated peptides

To investigate the potential use of multimeric peptides for increasing the binding to LPS, individual peptides are coated on an ELISA plate to high surface concentrations. Immobilization is performed by first coating the plate with streptavidin and then binding the peptides via their N-terminal biotin groups. Thus, 100 μ l streptavidin (Boehringer Mannheim GmbH; 10 μ g/ml in PBS) is used for coating followed by washing, blocking (10 min.) with PBS/0.1% Tween and a 30 min. incubation with 100 μ l of purified synthetic peptides (1 μ g/ml or 10 μ g/ml in PBST) labelled at the N-terminus with biotin. After washing with PBS/0.1% Tween the peptides are incubated for 1 hr with FITC-labelled LPS (SIGMA; Salmonella enteritidis; 0.5 μ g/ml in PBS/0.1% Tween). After washing with PBS/0.1% Tween, the ELISA plate is incubated with 100 μ l of an anti-FITC antibody conjugated to alkaline phosphatase (SIGMA; 1:2500 diluted in PBS/0.1% Tween) and washed with PBS/0.1% Tween and 100mM Tris pH 9.5. p-Nitrophenyl-phosphate (2 mg/ml in 100mM Tris pH 9.5) is used as a substrate for alkaline phosphatase. The ELISA is read at 405nm. All steps are done at room temperature.

As expected, LALF-14, LALF-11, LALF-10, LBP-14 and MS-21 showed the highest binding affinity to LPS (see Figure 12). Peptides which bind lipid A slightly above background level as determined in the alternative ELISA format, such as RETL-10, LBP-10-1 or LBP-10-2, show binding in this format clearly above (2-3 fold) background. This indicates that oligomeric binding sites for LPS can provide higher LPS binding activity.

Example 5: Competition of LALF: lipid A binding by peptides

To investigate the specificity of peptides in binding lipid A and LPS, competition experiments with known endotoxin binding

proteins such as LALF and LBP and the antibiotic polymyxin B are carried out. Thus an ELISA plate (NUNC, Polysorp 96U) is coated for 90 min. at 37°C with 100 μ l lipid A in PBS (0.25 - 0.3 μ g/ml) or lipopolysaccharide in PBS (0.25 - 0.3 μ g/ml). All further steps are done at room temperature. After washing and blocking (10 min.) with PBS/0.1% Tween, the solid phase is incubated for 1 hr with 100 μ l of increasing amounts (0.01 μ g/ml - 100 μ g/ml in PBS/0.1% Tween) of unlabelled or biotin-labelled peptides mixed with an endotoxin binding protein (LALF or LBP; 0.2 μ g/ml in PBS/0.1% Tween). After washing with PBS/0.1% Tween, the ELISA plate is incubated for 45 min. with 100 μ l of a rabbit antiserum against LALF or LBP, respectively. After washing with PBS/0.1% Tween the ELISA plate is incubated with 100 μ l anti-rabbit antibody conjugated to alkaline phosphatase (SIGMA; 1:10000 diluted in PBS/0.1% Tween) and washed with PBS/0.1% Tween and 100mM Tris pH 9.5. p-Nitrophenyl-phosphate (2 mg/ml in 100mM Tris pH 9.5) is used as a substrate for alkaline phosphatase. The ELISA is read at 405nm.

If assaying for LALF-lipid A binding, increasing amounts of peptide should lead to a decrease of detectable LALF bound to lipid A (see Figure 13). Polymyxin B is used as a positive control, and at sufficiently high concentration is able to displace LALF almost completely from immobilized lipid A. A control peptide and lysozyme, also known to bind lipid A and LPS, are not able to compete with LALF. Of the peptides based on the LALF sequence, LALF14, LALF-11 and L-10 are as capable as polymyxin B in competing the LALF/lipid A binding, indicating a similar LPS binding activity as polymyxin B, while RETL-10 only weakly competes with LALF.

At 100 μ g/ml, LALF-14, and polymyxin B compete with LALF for lipid A binding up to 95%, while a control peptide or lysozyme compete to 10% only. Of the peptides based on LBP, H-14 competes with LALF for lipid A binding as effectively as LALF-14 or polymyxin B, while only at the highest

concentrations do LBP-10-1 and H-10 inhibit the LALF lipid A binding. BPI-14 competes to a lesser extent compared with LALF-14, H-14 or polymyxin B. Of peptides based on the generalized lipid A binding motif, MS-21 competes with LALF for binding to lipid A to almost 80% while MS-22 is similar to BPI-14. PolP-1 (I-K-T-K-K-F-L-K-K-T), a peptide based on polymyxin B and shown to bind lipopolysaccharide and neutralize its toxicity (Rustici et al.. *Science* 259 (1993), 361-365), hardly competes with LALF for lipid A binding.

These data are presented in bar graph form in Figure 14 for a given concentration of peptide.

Example 6: Competition of LBP : lipid A binding by peptides

The ability of the peptides to compete with LBP for binding to LPS is determined in the same way as in Example 5, except that LALF is replaced with LBP (see Figure 15). The result of this experiment is, with one exception, very similar to the result in Figure 14. As shown in Figure 15, LALF-14, L-10 and H-14 are the most potent inhibitors of the LBP-lipid A binding. In contrast to the result observed with LALF, in this case polymyxin B is not able to compete with LBP for binding to lipid A.

Example 7: Competition of LBP-14: lipid A binding by peptides and proteins

An ELISA plate (NUNC, Polysorp 96U) is coated for 90 min. at 37°C with 100 μ l lipid A in PBS (0.2 - 0.3 μ g/ml). All further steps are done at room temperature. After washing and blocking (10 min.) with PBS/0.1% Tween, the solid phase is incubated for 1 hr with 100 μ l of increasing amounts (0.01 μ g/ml - 10 μ g/ml) of unlabelled peptides or proteins mixed with a biotin-labelled peptide (1 μ g/ml in PBST/0.1% Tween). After washing with PBS/0.1% Tween, 100 μ l streptavidin conjugated to alkaline phosphatase (Boehringer Mannheim GmbH,

1:10000 diluted in PBS/0.1% Tween) is added to the wells. This incubation is followed by washing with PBS/0.1% Tween and 100mM Tris pH 9.5. p-Nitrophenyl-phosphate (2 mg/ml in 100mM Tris pH 9.5) is used as a substrate for alkaline phosphatase. The ELISA is read at 405nm.

CD14 is used to compete the peptide-lipid A binding. The principle of such a binding assay is the same as for the LALF- or LBP-lipid A competition assays in which a constant amount of detectable peptide or protein is competed by an increasing amount of another peptide or protein. Instead of detecting LALF, bound biotin-labelled peptide is detected with streptavidin conjugated to alkaline phosphatase, and the labelled peptide concentration is kept constant while the unlabelled peptide or protein amount is increased. The binding of LBP-14 to lipid A binding is strongly competed by LALF and CD14, while polymyxin B shows only weak competition activity at the highest concentration used (see Figure 16). PolP-1 is only slightly above the background determined by lysozyme as competitor. A very similar result is observed when LALF-14 is used instead of LBP-14. These results indicate that the peptides LBP-14 and LALF-14 are able to compete with CD14 for lipid A binding.

Example 8: Influence of serum on peptide-lipid A binding

To determine the effect of serum proteins on peptide-lipid A binding, the interaction of labelled peptides is measured in an ELISA format in the presence of serum concentrations of 1% and 10% and compared with binding in buffer or medium. For all peptides tested, LALF-14, LALF-10, LBP-14, LBP-10-1 and BPI-14, the lipid A binding activity decreases with increasing serum concentration, but the peptides are still able to bind lipid A at 10% serum (see Figure 17). As control, the influence of serum on the LALF-lipid A binding was investigated, and a serum-dependent decrease of the LALF-lipid A binding is observed.

Example 9: Influence of serum on the competition of the LALF: lipid A binding by peptide

To investigate whether the specificity of the peptide-lipid A binding is influenced by serum, competition experiments are performed in which LALF-lipid A binding is compared in PBS/0.1% Tween and serum. In all cases only a slight decrease (ca. 5%) of the competition capacity of the peptides in the presence of 10% serum is observed compared to 0% serum (see Figure 18). However the peptides that compete efficiently with LALF for lipid A binding in buffer, such as LALF-14, LBP-14 and polymyxin B, which was used as a control, are also inhibiting in the presence of 10% serum. BPI-14 competes with LALF for lipid A binding to a lesser extent in the presence of 10% serum, and RETL-10 or the polymyxin derived peptide Pol P1 only inhibit slightly above background.

Example 10: Limulus amebocyte Lysate assay

The Limulus amebocyte Lysate test (gelling assay; sensitivity 0.125 EU/ml) and the Chromogenic Limulus amebocyte Lysate test (sensitivity 0.06 EU/ml) are performed according to the manufacturer's instruction (Bio*Whittaker, Walkersville, Maryland) using E.coli 055:B5 lipopolysaccharide. For neutralisation of LPS, peptides (0.1-10 µg/ml) and LPS are incubated for 15 min. at 37°C and then added to the Limulus lysate. In the gelling assay, the positive controls, LALF and polymyxin B, inhibit the assays, the control peptide (control) does not (see Figure 19). L-10, LALF-14, LBP-14, and BPI-14 are also able to inhibit the lysate assay, indicating neutralizing activity (Figure 19). The chromogenic assay allows quantification of the lipopolysaccharide neutralizing capacity of the peptides. LALF and polymyxin B inhibit the reaction up to 95%. Of the peptides, L-10, LALF-14, and LBP14 are best inhibiting (up to 79%). BPI-14 inhibits the chromogenic assay up to 63%, LBP-10-1, a weak

competitor of LALF- and LBP-lipid A binding, inhibits the assay up to 50%, while Pol P1, known to inhibit the gelling assay, inhibits the chromogenic assay only up to 25%.

Example 11: Inhibition by peptides of LPS-mediated TNF release by monocytes

Monocytes are purified with a ficoll gradient ($d=1.077$) from whole blood by centrifugation for 20 min. at 2200 rpm at room temperature. Ficoll is removed by washing 3 times with PBS. Purified monocytes are counted and diluted to 2×10^6 cells/900 μ l in medium (RPMI+) or medium with 0.1%-10% human serum. For TNF induction, 2×10^6 monocytes (in 900 μ l medium or medium with serum) and 100 μ l of LPS (Re-LPS F515; 0.1ng/ml-10ng/ml) or mixtures of LPS with peptides (10 μ g/ml) (preincubated for 15 min. at 37°C) are incubated in a 24 well plate (NUNC) for 2 to 5 hr. The supernatant is taken off and spun twice for 2 min. at 1500 rpm, once for 5 min. at 15000 rpm and stored at -20°C for TNF determination. The induced TNF is assayed by ELISA according to the manufacturer's instruction (BioSource International, California) using a 50 μ l sample of thawed supernatant.

L-10 and LBP-14 show 55% inhibition of TNF release, under the same conditions as polymyxin B shows 95% inhibition of TNF release (see Figure 20).

Claims

1. An LPS-binding peptide comprising an LPS-binding domain comprising at least:
 - (a) the amino acid sequence 1-2-3-4-5-6-7-8, wherein the numbers represent any of the following amino acids:
 - 1 = a polar or positively charged amino acid, preferably
C, H, K, N, Q, R, S, T, W, or Y;
 - 2 = a hydrophobic amino acid, preferably
A, F, H, I, L, M, V, or W;
 - 3 = a basic amino acid, preferably H, K, or R;
 - 4 = a hydrophobic or positively charged amino acid, preferably
A, F, H, I, K, L, M, R, V, or W;
 - 5 = a hydrophobic, polar, or positively charged amino acid, preferably
A, C, F, H, I, K, L, M, N, Q, R, S, T, V, W, or Y;
 - 6 = a positively charged amino acid, preferably K or R;
 - 7 = A hydrophobic, polar, or positively charged amino acid, preferably
A, C, F, H, I, K, L, M, N, Q, R, S, T, V, W, or Y;
 - 8 = a hydrophobic or positively charged amino acid, preferably
A, F, H, I, K, L, M, R, V, or W;
 - (b) a corresponding inverse amino acid sequence; or
 - (c) a variation of said amino acid sequence (a) or (b) capable of effectively binding to LPS.
2. The LPS-binding peptide according to claim 1, wherein said amino acid sequence (a) is any combination of the amino acids seen in the LPS-binding loops of LALF, LBP, or BPI, namely:

- 1 = T or R or K
- 2 = F or W
- 3 = R or K
- 4 = R or V or A
- 5 = L or R or Q
- 6 = K
- 7 = W or S or R
- 8 = K or F

3. The LPS-binding peptide according to claim 1 or 2 with the additional feature that the N-terminus is extended by two or more amino acids denoted -2 and -1 in which amino acid -2, which is the new N-terminus, is taken from the set R, K, H, N and Q, and amino acid -1 is any amino acid.
4. The LPS-binding peptide according to any one of claims 1 to 3 with the additional feature that the C-terminus is extended by addition of cysteine, and the N-terminus is extended by two or more amino acids denoted -2 and -1 in which amino acid -2, which is the new N-terminus, is taken from the set R, K, H, N and Q, and amino acid -1 is cysteine, the two cysteines being linked by a disulphide bond.
5. The LPS-binding peptide according to claim 1 or 2, wherein said amino acid sequence (a) is the sequence TFRRLKWK.
6. The LPS-binding peptide according to claim 1 or 2, wherein said amino acid sequence (a) is the sequence RWKVRKSFFKLQ.
7. The LPS-binding peptide according to claim 1 or 2, wherein said amino acid sequence (a) is the sequence KWKAQKRFLKMS.
8. The LPS-binding peptide according to any one of claims 1 to 7 which is a linear peptide.
9. The LPS-binding peptide according to any one of claims 1 to 7 which is constrained to adopt a circular conformation by an intramolecular interaction.

10. The LPS-binding peptide according to claim 9 wherein said interaction is a disulfide bond.
11. The LPS-binding peptide according to claim 10 having the amino acid sequence CHYRIKPTFRRLKWKYKGKFWC, CTFRRLKWKC, CRWKVRKSFFKLQC, CRWKVRKSFC, CKWKAQKRFLKMSC, or CKWKAQKRFC wherein the peptide is stabilized by a disulfide bond formed between the terminal cysteine residues.
12. The LPS-binding peptide according to any one of claims 1 to 11 which is detectably labelled.
13. A set of LPS-binding peptides each comprising one or more LPS-binding domains having one of the amino acid sequences according to any one of claims 1 to 12.
14. A DNA sequence encoding a peptide according to any one of claims 1 to 11.
15. A recombinant vector containing a DNA sequence according to claim 14.
16. A microorganism containing a recombinant vector according to claim 15.
17. A method for the production of an LPS-binding peptide according to any one of claims 1 to 12, comprising culturing a microorganism according to claim 16 and recovering said peptide or a fusion protein containing it from the medium.
18. A pharmaceutical composition comprising effective amounts of an LPS-binding peptide according to any of claims 1 to 11 or the set of LPS-binding peptides according to claim 13, optionally in combination with a pharmaceutically acceptable carrier and/or diluent.

19. The pharmaceutical composition according to claim 18 for the treatment of Gram-negative sepsis.
20. The pharmaceutical composition according to claim 18 for the treatment of Gram-positive sepsis.
21. The pharmaceutical composition according to claim 18 for the treatment of bacterial infections.
22. The pharmaceutical composition according to claim 18 for the treatment of fungal infections.
23. The pharmaceutical composition according to claim 18 for treatment of heparin-mediated anti-coagulation.
24. The pharmaceutical composition according to claim 18 for the inhibition of angiogenesis.
25. The pharmaceutical composition according to claim 18 for the inhibition of tumour cell proliferation.
26. The pharmaceutical composition according to claim 18 for the inhibition of endothelial cell proliferation.
27. A diagnostic kit containing an LPS-binding peptide according to any one of claims 1 to 12, or a set of LPS-binding peptides according to claim 13.
28. The diagnostic kit according to claim 27 for the determination of LPS or for the diagnosis of septic conditions.
29. The peptides of claims 1 to 12 or the set of LPS-binding peptides according to claim 13, immobilized on a solid support.

30. A method of removing LPS from solution using the immobilized peptides of claim 29.
31. The method according to claim 30 in which said immobilized peptides are used for the removal of bacteria from solution.

(54) Title: INDUCING ANTIBODY RESPONSE AGAINST SELF-PROTEINS WITH THE AID OF FOREIGN T-CELL EPITOPES

(57) Abstract

A novel method for utilizing the immune apparatus to remove and/or down-regulate self-proteins consists in inserting one or more foreign T-cell epitopes in such proteins by molecular biological means, thereby rendering said proteins immunogenic. The modulated self-proteins can be used as autovaccines against undesirable proteins in humans or animals, said autovaccine being useful as vaccines against a number of diseases, e.g. cancer, chronic inflammatory diseases, rheumatoid arthritis, inflammatory bowel diseases, allergic symptoms or diabetes mellitus.

Cloning strategy for murine TNF α mutants.

INDUCING ANTIBODY RESPONSE AGAINST SELF-PROTEINS WITH THE AID OF FOREIGN T-CELL EPITOPES

5 Background of the invention

This invention concerns a novel method for utilizing the immune apparatus to remove and/or down-regulate self-proteins, the presence of which somehow is unwanted in the individual. These could be proteins which are causing disease and/or other undesirable symptoms or signs of disease. Such proteins are removed by circulating auto-antibodies which specifically are induced by vaccination. This invention describes a method for developing such autovaccines.

Introduction

Physiologically, the vertebrate immune system serves as a defence mechanism against invasion of the body by infectious objects such as microorganisms. Foreign proteins are effectively removed via the reticuloendothelial system by highly specific circulating antibodies, and viruses and bacteria are attacked by a complex battery of cellular and humoral mechanisms including antibodies, cytotoxic T lymphocytes, Natural Killer cells, complement etc. The leader of this battle is the T helper (T_H) lymphocyte which, in collaboration with the Antigen Presenting Cells (APC), regulate the immune defence via a complex network of cytokines.

Normally the individual's own proteins (the so-called self- or autoproteins) are not attacked by the immune apparatus. The described events thus generally are beneficial to the individual, but in rare cases the process goes wrong, and the immune system turns towards

- 2 -

the individual's own components, eventually leading to an autoimmune disease.

5 The presence of some self-proteins is, however, inexpedient in situations where they, in elevated levels, induce disease symptoms. High levels of immunoglobulins of the IgE class are e.g. known to be important for the induction of type I allergy, and tumor necrosis factor α (TNF α) is known to be able to cause cachexia in cancer
10 patients and patients suffering from other chronic diseases (H.N. Langstein et al., Cancer Res. 51, 2302-2306, 1991). TNF α also plays important roles in the inflammatory process (W.P. Arend et al., Arthritis Rheum. 33, 305-315, 1990). Hormones in sex-hormone dependent
15 cancer are other examples of proteins which are unwanted in certain situations. This invention concerns a method for the development of autovaccines against such proteins.

Others have developed autovaccines by conjugating self-
20 proteins or appropriate synthetic peptides derived from these to large, foreign carrier proteins. Talwar et al. (G.P. Talwar et al, Int. J. Immunopharmacol. 14, 511-514, 1992) have been able to prevent reproduction in women using a vaccine consisting of a conjugate of human
25 chorionic gonadotropin and tetanus toxoid. There are also other examples of such autoimmunogenic conjugates which have been used therapeutically in man and in animal models (D.R. Stanworth et al., Lancet 336, 1279-1281 (1990)). In the present invention the production of such
30 conjugates between the self-proteins and foreign proteins is not necessary in order to obtain strong autoantibody responses. This has several advantages.

The technical field

35

T_H lymphocytes recognize protein antigens presented on the

- 3 -

surface of the APC. They do not recognize, however, native antigen per se. Instead, they appear to recognize a complex ligand consisting of two components, a "processed" (fragmented) protein antigen (the so-called T cell epitope) and a Major Histocompatibility Complex class II molecule (O. Werdelin et al., Imm. Rev. 106, 181 (1988)). This recognition eventually enables the T_H lymphocyte specifically to help B lymphocytes to produce specific antibodies towards the intact protein antigen (Werdelin et al., supra). A given T cell only recognizes a certain antigen-MHC combination and will not recognize the same or another antigen presented by a gene product of another MHC allele. This phenomenon is called MHC restriction.

Self-proteins are also presented by the APC, but normally such fragments are ignored or not recognized by the T helper lymphocytes. This is the reason why individuals generally do not harbour autoantibodies in their serum.

It is, however, possible artificially to induce antibodies against self-proteins. This can be done, as previously mentioned, by covalent conjugation of the self-protein to an appropriate carrier protein as e.g. tetanus toxoid or key-hole limpet hemocyanin. During the processing of such conjugates in the APC, the necessary T_H lymphocyte stimulatory epitopes are provided from the foreign protein eventually leading to the induction of antibodies against the self-protein as well as against the carrier protein. One disadvantage of using this principle is, however, that the antibody response towards the self-protein will be restricted due to shielding of epitopes by the covalently linked carrier protein. Another disadvantage is the increased risk of inducing allergic side-effects due to the contemporary induction of a very strong antibody response against the foreign carrier protein. This strong antibody response might also be the reason why this method

- 4 -

is not as efficient as observed in the method according to the invention.

Other researchers have coupled a single peptide T cell epitope chemically to a self-protein and managed to induce an autoantibody response with MHC restriction to that particular T cell epitope (S. Sad et al., Immunology 76, 599-603, 1992). This method seems to be more effective compared to coupling of large carrier proteins. However, it will only induce antibodies in a population expressing the appropriate MHC molecules. This means that a rather large number of T cell epitopes has to be coupled to the self-protein which will eventually disturb the B cell epitopes on the surface of the self-protein. Extensive conjugation of proteins may furthermore have the opposite effect with regard to immunogenicity (international patent application No. WO 87/00056) and the surface exposed peptide T cell epitopes may be destroyed by proteolytic enzymes during antigen processing (S. Mouritsen, Scand. J. Immunol. 30, 723, 1989), making that method less efficient than the method of the invention. By this method autoantibodies can be induced within a few weeks (Example 2). Finally, the exact structure of such multi-conjugated self-proteins will not be chemically and pharmaceutically well-defined.

The induction of autoantibodies against TNF α by the method of the present invention has been directly compared to the autoantibody response induced when using a conjugate of TNF α and E. coli proteins, which must contain small single T cell epitope peptides as well as larger foreign carrier proteins. The autoantibody response induced by the method of the invention was induced several weeks earlier and was furthermore of a higher titer (Example 4).

35

- 5 -

Recently an improved method has been proposed for breaking the B cell autotolerance by chemical conjugation of B and optionally also peptide T cell epitopes to a high molecular weight dextran molecule (international patent application No. WO 93/23076). The disadvantages mentioned above, however, also hold true for said method, which anyway is clearly different from the method of the present invention.

10 Although it has been proposed previously that a well known strong T cell epitope could be inserted into a foreign protein using recombinant DNA technology (EP-A2-0 343 460) or synthetically into a peptide (WO 90/15627) in order to increase an antibody response towards that protein or peptide, it has not been proposed that this could be done with the purpose of breaking the autotolerance of the immune system. Using these methods for induction of auto-antibodies one a priori would expect the same rules to be true with regard to the above-mentioned limitations of the MHC restriction of the response. Surprisingly, however, by using the method of the invention, it is possible to induce and equally fast and even a stronger autoantibody response against TNF α despite the fact that the inserted T cell epitope used was not restricted to the MHC molecules of the immunized mice (Example 3). The reason for this observation is not clear but may be due to the appearance of new MHC binding segments in the mutagenized area in the self-protein. However, the experiment shown in example 6 demonstrates that this is probably not the case, since synthetic peptides representing overlapping regions of the implanted ovalbumin T cell epitope in ubiquitin did not bind strongly to any of the MHC class II molecules of the H-2^k mice in which this recombinant molecule was highly immunogenic (Example 5).

35

- 6 -

Most of the potential MHC class II binding segments of a protein are normally cryptic and will not be presented to the host T cells by the antigen presenting cells (S. Mouritsen et al, Scand. J. Immunol. 34, 421, 1991). The
5 observed lacking correspondence between the MHC restriction of the inserted T cell epitope and the restriction of the antibody response could perhaps be due to a general disturbance of the intra-molecular competition of binding to MHC molecules by different self-protein segments. Using
10 the herein described method non-tolerized self-protein segments may be presented to the T cells leading to breaking of the T cell as well as the B cell autotolerance towards the protein. In all the examples described below, a fragment of the self-protein was substituted with a
15 foreign T cell epitope. This deletion followed by a substitution with an other protein fragment minimally obscure the tertiary structure of the self-proteins, but may also contribute strongly to the disturbance of said intra-molecular competition of the MHC class II binding self-
20 segments. This concept is therefore clearly different from the above-mentioned mechanisms and methods. Independently of the operating mechanism of action by the herein described method, it is more technically advantageous compared to the known methods for breaking the B cell auto-
25 tolerance, since it is possible to induce antibodies in a broad population of MHC molecules by insertion of a minimal number of different foreign T cell epitopes.

The present invention thus concerns the surprising fact
30 that injection of recombinant proteins, which have been appropriately modulated by the insertion of one or more foreign T cell epitopes, induces a profound autoantibody response against said proteins. Surprisingly the antibody response induced is not necessarily restricted to the
35 inserted T cell epitope. By inducing minimal tertiary structural changes in the highly conserved self-protein

- 7 -

ubiquitin, as well as in $\text{TNF}\alpha$, foreign T cell epitopes having a length of 12-15 amino acids were inserted using genetic engineering methods. These recombinant proteins were purified, emulsified in adjuvant and injected into mice. Within only one week an autoantibody response against ubiquitin could be detected in serum from these mice. Non-modified, recombinant ubiquitin treated and injected in the same way was not able to induce a response.

10

By using this principle for developing vaccines against undesirable proteins, the risk of inducing allergic side-effect is reduced, and toxic self-proteins such as $\text{TNF}\alpha$ can simultaneously be detoxified by removing or mutating biologically active protein segments. The epitope-shielding effect described above is not a problem, and autoantibodies against ubiquitin were induced much faster as compared to the known technique, in which the self-protein is conjugated to a carrier protein or peptide. Importantly, by this method it furthermore seems possible to temporarily break the autotolerance of the T cells as well as that of the B cells of the individual, and such recombinant proteins will be self-immunogenic in a large population expressing many different MHC class II molecules.

25

The vaccine of the invention consists of one or more self-proteins modulated as described above and formulated with suitable adjuvants, such as calcium phosphate, saponin, quil A or biodegradable polymers. The modulated self-proteins may be prepared as fusion proteins with suitable, immunologically active cytokines, such as GM-CSF or interleukin 2.

35

The autovaccine may i.a. be a vaccine against $\text{TNF}\alpha$ or γ -interferon for the treatment of patients with cachexia, e.g. cancer patients, or a vaccine against IgE for the

- 8 -

treatment of patients with allergy. Furthermore, it may be a vaccine against $TNF\alpha$, $TNF\beta$ or interleukin 1 for the treatment of patients with chronic inflammatory diseases.

5 The invention is illustrated in the following examples.

Example 1. Cloning of foreign T cell epitopes into a gene coding for ubiquitin.

10

An overview of this procedure is shown in fig. 1 using the T cell epitope MP7 as example. The gene sequences representing MP7 (MP7.1-C and MP7.1-NC) were synthesized as two complementary oligonucleotides designed with
15 appropriate restriction enzyme cloning sites. The amino acid sequence of MP7 is PELFEALQKLFKHAY. The oligonucleotides were synthesized using conventional, automatic solid phase oligonucleotide synthesis and purified using agarose gel electrophoresis and low melting agarose. The desired
20 bands were cut out from the gels, and known quantities of oligonucleotides were mixed, heated to 5°C below their theoretical melting point (usually to approximately 65°C) for 1-2 hours, and slowly cooled to 37°C. At this temperature the hybridized oligonucleotides were ligated
25 to the vector fragments containing part of the ubiquitin gene. The subsequent analysis of positive clones using restriction fragment analysis and DNA sequencing was done by conventional methods ("Molecular Cloning", Eds.: T. Maniatis et al. 2 ed. CSH Laboratory Press, 1989).

30

Example 2. Induction of autoantibodies against ubiquitin by vaccination with modified ubiquitin molecules.

35

Genes containing the foreign T cell epitopes were expressed in E. coli strain, AR58 under control by the

- 9 -

heat sensitive λ repressor regulated promotor. Expression of the recombinant ubiquitin proteins were verified using a polyclonal anti-ubiquitin antibody and Western-blotting ("Antibodies", Eds.: D. Harlow et al., CSH Laboratory Press, 1988). The recombinant proteins were purified using conventional methods (Maniatis et al., supra).

Mice were injected i.p. with 100 μ g of ubiquitin or its analogs in PBS emulsified in Freund's Complete adjuvant. Booster injections of the same amount of antigen emulsified 1:1 in Freund's Incomplete adjuvant were performed i.p. at days 14 and 28. Five Balb/c mice in each group were examined and blood samples were examined for the presence of anti-ubiquitin antibodies on day 7, 14, 21, 28, 35, and 42 using conventional ELISA methodology.

The results exemplified by the antibody response against two different ubiquitin molecules containing the T cell epitopes OVA(325-336) and HEL(50-61), respectively, are shown in fig. 2. The amino acid sequence of the inserted OVA(325-336) epitope is: QAVHAAHAEINE and the amino acid sequence of the HEL(50-61) epitope is STDYGILQINSR.

A clear antibody response against native ubiquitin could be detected within only one week from the first injection of antigen reaching a maximum within 2 weeks. Anti-ubiquitin antibodies produced in rabbits by covalently conjugating ubiquitin to bovine immunoglobulin reached maximum values after a much longer immunization period (data not shown).

The antibody response against self-proteins can be increased even more by injecting self-proteins containing foreign T cell epitopes, as described in example 1, as fusion proteins with immunologically active cytokines such as e.g. granulocyte and monocyte colony stimulating factor

- 10 -

(GM-CSF) or interleukin 2.

Example 3. Induction of autoantibodies against tumor
necrosis factors (TNF) by vaccination with appropriately
5 modified TNF molecules.

The gene coding for the structural part of the murine TNF α
protein (MR101) was obtained by Polymerase Chain Reaction
10 (PCR) cloning of the DNA. In the MR103 TNF α mutant the
ovalbumin (OVA) H-2^d restricted T cell epitope sequence
325-334 (QAVHAAHAET) replaces the amino acids 26-35 in the
cloned TNF α sequence, a substitution of an amphiphatic α -
helix. Substitutions in this region of the TNF α detoxifies
15 the recombinant protein (X. Van Ostade et al., Nature 361,
266-269, 1993). In the MR105 TNF α mutant the H-2^k re-
stricted T cell epitope from hen eggwhite lysozyme (HEL),
amino acid sequence 81-96 (SALLSSDITASVNCAK) replaces the
amino acids 5-20 in the cloned TNF α sequence. In the MR106
20 TNF α mutant the same epitope, amino acid sequence 81-95
(SALLSSDITASVNCA) replaces the amino acids 126-140 in the
cloned TNF α sequence. The genetic constructions are
described in Fig. 3. Different techniques compared to the
technique described in example 1 were used for exchanging
25 parts of the TNF α gene with DNA coding for T cell epi-
topes. The MR105 and 106 constructs were made by intro-
ducing the mutant sequence by PCR recloning a part of the
TNF α gene flanking the intended site for introducing the T
cell epitope. The mutant oligonucleotide primer contained
30 both a DNA sequence homologous to the TNF α DNA sequence
as well as a DNA sequence encoding the T cell epitope. The
PCR recloned part of the TNF α gene was subsequently cut
with appropriate restriction enzymes and cloned into the
"wild type" MR101 gene. the MR103 construction was made by
35 a modification of the "splicing by overlap extension" PCR
technique (R. M. Horton et al., Gene 77, 61, 1989). Here

- 11 -

two PCR products are produced, each covering a part of the TNF α gene, and additionally each PCR product contains half of the T cell epitope sequence. The complete mutant TNF α gene was subsequently made by combining the two PCR products in a second PCR. Finally, the complete genetic constructions were inserted into protein expression vectors. Subsequently, all genetic constructions were analyzed by restriction fragment analysis and DNA sequencing using conventional methods ("Molecular Cloning", Eds,: T. Maniatis et al. 2.ed. CSH Laboratory Press, 1989). The recombinant proteins were expressed in E.coli and purified by conventional protein purification methods.

Groups of BALB/c (MHC haplotype, H-2^d) and C3H (MHC haplotype, H-2^k) mice, respectively, were immunized subcutaneously with 100 μ g of semi-purified MR103 and MR106 emulsified in Freund's complete adjuvant. Every second week the immunizations were repeated using incomplete Freund's adjuvant. All mice developed an early and strong antibody response against biologically active MR101. This was measured by a direct ELISA method using passively adsorbed 100% pure MR101 (Fig. 4). Control mice immunized with MR101 and PBS, respectively, showed no antibody reactivity towards MR101.

Strikingly, the response was not MHC restricted corresponding to the implanted T cell epitopes, since both mice strains responded well to MR103 and MR106 (Fig. 4). Taken together these results illustrate (a) the ability of the method of the invention to induce autoantibodies towards a secreted autoproduct and (b) the improved efficiency of the herein described method with regard to inducing a response in a broader MHC population than predicted by the MHC binding ability of the inserted T cell epitopes. The immune response against the recombinant proteins MR103 and MR106 was much stronger and more high-titered compared to

- 12 -

aldehyde conjugated MR101 (see Example 4).

Example 4. Induction of autoantibodies against TNF α by the method of the invention compared to conjugation to E. coli proteins.

Semi-purified recombinant murine TNF α (MR101) was conjugated to E. coli proteins in PBS, pH 7.4, using 0.5% formaldehyde. Conjugation of the proteins was confirmed by SDS-PAGE. These conjugates were subsequently used for immunization of C3H mice. Another group of C3H mice was vaccinated only with semi-purified non-conjugated MR105, and about 100 μ g of recombinant TNF α were emulsified 1:1 in Freund's complete adjuvant and injected subcutaneously in each mouse. MR105 is biologically inactive as judged by the L929 bioassay for TNF α . In subsequent immunizations every second week incomplete Freund's adjuvant was used. Both groups eventually developed autoantibodies against highly purified biologically active MR101 as determined by ELISA, but the immune response against non-conjugated MR105 was induced earlier and was of a higher titer (Fig. 5).

Example 5. The possible MHC class II binding of peptides representing overlapping sequences of self-protein as well as of the ovalbumin T cell epitope inserted in ubiquitin.

Peptide-MHC complexes were obtained by incubating ¹²⁵I-labelled peptide (10-100 nM) with affinity purified MHC class II molecules (2-10 μ M) at room temperature for 3 days (S. Mouritsen, J. Immunol. 148, 1438-1444, 1992). The following peptides were used as radiolabelled markers of binding: Hb(64-76)Y which binds strongly to the E^k molecule and HEL(46-61)Y which binds strongly to the A^k

- 13 -

molecule. These complexes were co-incubated with large amounts of cold peptide (> 550 μ m) which is sufficient to inhibit totally all immunologically relevant MHC class II binding. Either the same peptides were used, or three different overlapping peptides were used, said peptides representing the flanking regions as well as the entire OVA(325-336) T cell epitope which was substituted into ubiquitin (see Example 2). The three peptides were: TITLEVEPSQAVHAA (U(12-26)), PSQAVHAAHAEINEKE (U(19-34)) and HAEINEKEGIPPDQQ (U(27-41)). The reaction buffer contained 8 mM citrate, 17 mM phosphate, and 0.05% NP-40 (pH 5) and peptide-MHC class II complexes were separated (in duplicate) from free peptide by gel filtration using G25 spun columns. Both the radioactivities of the excluded "void" volume and of the included volume were measured by gamma spectrometry. The competitive inhibition of maximal binding (in percent) by addition of cold peptide was calculated. The results are shown in Table I.

Table I.

Peptid/ MHC	Hb(64-76)	HEL(46-61)	U(12-26)	U(19-34)	U(27-41)
A ^k	28.6	<u>97.4</u>	35.3	44.6	7.8
E ^k	<u>92.6</u>	0.0	45.6	12.2	0.0

It can be seen that total inhibition of the binding of the radiolabelled peptides Hb(64-76)Y and HEL(46-61)Y to E^k and A^k respectively could only be achieved using cold versions of the same peptides. Although some inhibition of binding was seen by U(12-26) and U(19-434) using these extreme amounts of cold peptide, it is likely that the

- 14 -

affinity of these peptides to the H-2^k MHC class molecules is very low. Therefore this seems not to be sufficient to explain the strong immunogenicity in the H-2^k mouse strain of the ubiquitin analog containing the ovalbumin T cell
5 epitope. More likely, other and previously non-tolerized self-epitopes are presented to the T cell in these animals.

Example 6. Treatment of diabetes of inflammatory disease
10 by vaccination with appropriately modified TNF α molecules.

Genes coding for TNF α are modified by insertion of appropriate gene segments coding for T cell epitopes derived
15 from e.g. tetanus toxin or influenza hemagglutinin. Such genes are expressed in appropriate expression vectors in e.g. E. coli or insect cells. The recombinant TNF α proteins were purified using conventional methods ("Molecular Cloning", Eds.: T. Maniatis et al. 2. ed. CSH Laboratory
20 Press, 1989).

Optionally such recombinant proteins can be coupled to immunologically active cytokines such a GMCSF or interleukin 2.

25 The recombinant proteins can be formulated with appropriate adjuvants and administered as an anti-TNF α vaccine to patients suffering from diseases where TNF α is important for the pathogenesis. The induced anti-TNF α
30 antibodies will thereby affect the diseases.

One example of said diseases is the chronic inflammatory diseases such as e.g. rheumatoid arthritis where TNF α is believed to play an important role (reviewed in: F.M.
35 Brennan et al., Br. J. Rheumatol. 31, 293-298, 1992). TNF α is also believed to play an important role in the cachec-

- 15 -

tic conditions seen in cancer and in chronic infectious diseases such as AIDS (reviewed in M. Odeh. J. Intern. Med. 228, 549-556, 1990). It is also known that TNF participates in septic shock (reviewed in: B.P. Giroir, Crit. Care. Med., 21, 780-789, 1993). Furthermore, it has been shown that TNF α may play a pathogenetic role in the development of type II diabetes mellitus (CH Lang et al., Endocrinology 130, 43-52, 1992).

- 16 -

Fig. 4. Induction of TNF α autoantibodies by vaccination of Balb/c or C3H mice with semipurified MR103 and MR106. The antibody titers were measured by ELISA and expressed as arbitrary units (AU) referring to a strong standard anti-serum from one mouse. The plotted values represent a mean titer for 5 animals. Freund's complete adjuvant was used as adjuvant for the first immunization. All subsequent immunizations at 14 days intervals were done with Freund's incomplete adjuvant. Mice immunized in parallel with native MR101 in PBS did not develop detectable TNF α autoantibodies (data not shown). Non-detectable antibody titers were assigned the titer value 1.

Fig. 5. Anti TNF α autoantibodies induced by vaccination with non-conjugated MR105 and MR101 conjugated to E. coli proteins, respectively. C3H mice and Balb/c mice were immunized with both preparations. The immunizations, measurements and calculations of mean antibody titers were done as described in example 4.

☒ Further documents are listed in the continuation of Box C.☒ See patent family annex.

* Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application No.

PCT/DK 94/00318

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see next sheet

1. ☒ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

The additional search fees were accompanied by the applicant's protest.

No protest accompanied the payment of additional search fees.

- 1) Claims 1-3
A method for the modulation of self proteins by insertion of a T-cell epitope into the protein and an autovaccine.
- 2) Claims 4,5,7 and 8
An autovaccine comprising a fusion protein of a foreign T-cell epitope and a self protein prepared as fusion proteins with suitable, immunologically active cytokines.
- 3) Claim 6
Autovaccine comprising a foreign T-cell epitope inserted in IgE

AMELIORATION OF AMNESIA IN ALZHEIMER'S DISEASE CAUSED BY DEPOSITION OF
AMYLOID β PROTEIN

This application is a continuation of United States application Serial No. 08/127,904 filed 29 September 1993.

FIELD OF THE INVENTION

This invention relates to amelioration of amnesia in Alzheimer disease (AD) caused by deposition of amyloid β protein (A β) and, therefore, to attenuation of the disease process and consequential improvement of the quality of life for individuals suffering from AD. More particularly the invention relates to prevention of deterioration of memory and quality of life in AD patients by administration of the peptides Asp Phe Phe Val Gly (SEQ ID NO: 1), Gln Phe Val Gly (SEQ ID NO: 2), and Ala Ile Phe Thr (SEQ ID NO: 3) or amides or esters thereof. Administration of these substances to human individuals with AD can enhance memory and attenuate progression of the disease, in this way improving the quality of life.

DEFINITIONS

The following abbreviations are used:

A β = amyloid β protein

FAAT = footshock active avoidance training

ICV = intracerebroventricular

Ala = alanine

Cys = cysteine

Asp = aspartic acid

Glu = glutamic acid

Phe = phenylalanine

Gly = glycine

His = histidine

Ile = isoleucine

-2-

Lys = lysine
Leu = leucine
Met = methionine
Asn = asparagine
Pro = proline
Gln = glutamine
Arg = arginine
Ser = serine
Thr = threonine
Val = valine
Trp = tryptophan
Tyr = tyrosine

BACKGROUND OF THE INVENTION

Much data suggests that in Alzheimer disease (AD) there may be genetically and/or environmentally induced defects in the enzymatic machinery involved in degradation of amyloid precursor protein (APP) (for reviews, see refs. 1 and 2). Alternative splicing of mRNAs gives rise to at least five forms of APP, two of which possess a Kunitz-type protease inhibitory domain. Normal lysosomal processing of APPs involves highly coordinated sequences of desulfation, dephosphorylation, deglycosylation, and proteolytic splitting. The APPs may belong to a family of polypeptide precursors or polyproteins that upon processing give rise to a number of different bioactive peptides that may act individually or in concert to regulate cellular activation (3-5). The processing of the parent molecules and/or the extracellular secretion of the resulting subunits may vary with species, tissue, age, hormonal status, extent of phosphorylation (6), etc. Although the APPs may be cell-surface receptors (7, 8), some of the peptidic fragments derived from them may be ligands (9) for specific membrane sites.

-3-

To some extent in normal aging and to greater extent in AD and in adult Down syndrome, abnormal processing of APP gives rise to an insoluble self-aggregating 42-amino acid polypeptide designated as amyloid β protein ($A\beta$) that is found in amyloid (10-14). The extent of $A\beta$ deposition correlates with the degree of neuronal damage, cognitive impairment, and memory loss (15-18). Amyloid-like fibrils arise readily in vitro under physiological conditions even from the following smaller peptides homologous to $A\beta$: β -(1-28) (N-terminus residues 1 to 28), [Gln¹¹] β -(1-28), β -(12-18), and β -(18-28) (19-21). Extensive stacks of β -pleated sheets are formed from the latter peptide (21). Functional deficits arise in AD from damage to nerve circuitry per se, which is known to occur in late phases of the disease (22, 23). It also is possible that binding of $A\beta$ and related peptides to components of the extracellular matrix (e.g., proteoglycans (24)) or to receptors on endothelial, glial, or neuronal cells in particular brain regions could have disruptive effects on neuronal communications at earlier stages of the disease when the deposits of these substances are diffused and typical cytopathological evidence of AD often is absent.

It has been demonstrated (25) that $A\beta$ and, perhaps, smaller peptidic fragments thereof that are responsible for binding of $A\beta$ to cell membranes or components of the extracellular matrix may have amnestic effects upon appropriate administration to experimental animals. Hence, soluble peptides or structurally mimetic nonpeptidic substances can be devised to antagonize the binding of the $A\beta$ and thus alleviate some of the symptoms of AD not caused by actual physical destruction of neural circuitry. Progression may also be attenuated by such substances.

-4-

SUMMARY OF THE INVENTION

This invention involves the discovery that three peptides, Asp Phe Phe Val Gly (SEQ ID NO: 1), Gln Phe Val Gly (SEQ ID NO: 2), and Ala Ile Phe Thr (SEQ ID NO: 3), overcome the amnestic effects of β -(12-28), a peptide homologous to A β that is as potently amnestic as A β (25) and which shows amyloid-like aggregation similarly to A β (19-21). No other substances are known which serve this purpose.

DETAILED DESCRIPTION OF THE INVENTION

Screening of various peptides which neither are significantly amnestic nor memory-enhancing in memory-testing paradigms in mice resulted in the discovery of three peptides that blocked the amnestic effects of β -(12-28), a peptide homologous to A β . Administration of the peptides (SEQ ID NO: 1, SEQ ID NO: 2, SEQ ID NO: 3) or their esters or amides orally, subcutaneously, intravenously, transcutaneously, intrathecally, sublingually, rectally, or intracisternally leads to an amelioration of symptoms in Alzheimer disease by decreasing deposition of amyloid in the brain.

This discovery facilitates the development of substances that can antagonize binding of A β to neural structure and thus attenuate symptoms and progression of Alzheimer disease. Similarity in brain function in various mammals, including human beings, and previous neurological experience, indicates that the three peptides discovered to block the amnestic effects of β -(12-28) and derivatives and variants including esters and amides thereof will be effective therapeutic substances in human beings with Alzheimer disease. In no known instance have such substances been proposed for this purpose.

-5-

DESCRIPTION OF THE FIGURES

Figure 1 depicts an antagonism by Asp Phe Phe Val Gly (SEQ ID NO: 1) of amnestic effect of β -(12-28) when administered before or after β -(12-28) to groups of 15 mice each. SAL = physiological saline (sterile).

EXEMPLIFICATION OF THE INVENTION

Materials and Methods

Test Animals. After one week in the laboratory, CD-1 male mice obtained from Charles River Breeding Laboratories were caged individually 24-28 hours prior to training and remained singly housed until retention was tested one week later. Animal rooms were on a 12-hour light/dark cycle with lights going on at the hour of 0600. Median body weight was 35 g, with a range of 33-38 g. Mice were assigned randomly to groups of ten in the experiments reported in Table 1, groups of 14 in the experiments reported in Table 2, and groups of 15 in Figure 1 and were trained and tested between the hours of 0700 and 1500.

Peptides Tested. The peptides used in these studies were synthesized and analyzed to establish purity by standard methods at the Beckman Research Institute.

Peptides were dissolved in 8% vol/vol dimethyl sulfoxide and diluted to a final concentration of 0.001% dimethyl sulfoxide in saline. Upon testing for retention of FAAT after receiving post-training ICV administration of 2 μ l of the above vehicle the mean numbers of trials to criterion \pm standard error of the mean (SEM for well trained mice and weakly trained mice were 6.85 ± 0.20 and 9.07 ± 0.25 , respectively (see the paragraph below for definition of the two training paradigms).

The experiments below tested whether or not there were amnestic or memory-enhancing effects at 6 nmol of peptide per mouse.

-6-

Apparatus, training and Testing Procedures. The T-maze used for footshock active avoidance training (FAAT) consisted of a black plastic alley (46 cm long) with a start box at one end and two goal boxes (17.5 cm long) at the other. The start box was separated from the alley by a plastic guillotine door that prevented movement down the alley until training began. The alley was 12.5 cm deep and 9.8 cm wide. An electrifiable stainless steel rod floor ran throughout the maze.

Mice were not permitted to explore the maze before training. A block of training trials began when a mouse was placed in the start box. The guillotine door was raised and a muffled doorbell-type buzzer sounded simultaneously; footshock was 5 seconds later through a scrambled grid floor shocker (Colbourn Instruments, Model E13-08). The goal box first entered during the first set of trials was designated as "incorrect", and footshock was continued until the mouse entered the other goal box, which in all subsequent trials was designated "correct" for the particular mouse. At the end of each group of trials, the mouse was removed to its home cage.

As training proceeded, a mouse made one of two types of responses. A response latency longer than 5 seconds was classed as an escape from the footshock. A response latency less than or equal to 5 seconds was considered an avoidance, since the mouse avoided receiving a footshock. Two exclusion criteria were applied to reduce learning variability among mice, as follows. On the first training trials, mice with escape latencies greater than 20 seconds were discarded. Mice not having at least one errorless escape latency between 1.5 and 3.5 seconds on training trials 3 or 4 were excluded. The total

-7-

exclusions were fewer than 15%. Mice received five such training trials. One week after training and post-trial administration of vehicle alone or vehicle containing test substance, T-maze training was resumed until each mouse made five avoidance responses in six consecutive training trials (trials to criterion). The recall score was taken to be the percentage of tested mice remembering original training.

Well-trained animals (recall score approximately 80%) were used to determine whether or not administered substances could cause amnesia. In these instances, training was performed under conditions that tend to maximize learning (sound intensity, 65 decibels; footshock current, 0.35 mA; intertrial interval, 45 seconds). In the cases in which it was desired to detect whether or not there was an enhancing effect on memory, training conditions were adjusted so that the initial recall score in vehicle controls was only approximately 20% (sound intensity, 55 decibels; footshock current, 0.30 mA; intertrial interval, 30 seconds).

Surgical Procedure in Preparation for Intracerebroventricular (ICV) Administration of Substances. ICV injection was the mode of administration of test substances because this eliminates problems of differential penetration of the blood-brain barrier. The following procedure was performed 24-48 hours prior to training. A single hole was drilled through the skull over the third ventricle (-0.5 mm relative to bregma, 0.5 mm right of central suture) while the mouse, appropriately anesthetized with methoxyflurane, was held in a stereotaxic instrument. The third ventricle was chosen as site of ICV drug injection because only a single injection is required and the drug quickly

-8-

reaches limbic system structures, believed to be associated with memorial processes. Immediately after training, mice were anesthetized with enflurane, a short acting anesthetic, and given an ICV injection of 2 μ l of vehicle alone or test substance in vehicle delivered over a 30-second period through a 31-gauge needle attached to a 10- μ l syringe; the injection was given within 2-3 minutes after the training. Accuracy of injection was determined to be greater than 95% by dye injection, monitored regularly.

Statistical Treatment of Data. All of the results are expressed in terms of the mean and standard errors of the mean (SEM). Significance of overall effects of treatment was determined by one-way analysis of variance (ANOVA) run on trials to criterion. Dunnett's t-test was used to make multiple comparison of individual test groups with control groups. See Bruning, J.E., et al., in Computational Handbook of Statistics, 2d ed., Scott, Foreman and Co., Glenview, pp. 18-30, 122-124, 128-130 (1977). Statistical comparison among experimental groups were made by Bukey's t-test. See Winer, B.J., Statistical Principles in Experimentation Design, 2d ed., McGraw-Hill, New York, pp. 196-210, 397-402 (1971).

RESULTS

Three non-amnestic peptides block the amnestic effects of β -(12-28), a peptide homologous to β /A4). The following peptides tested under standard conditions in groups of 15 mice. Each were found to have no significant amnestic effect in the standard test with well-trained mice: Phe Phe (SEQ ID NO: 4), Val Val (SEQ ID NO: 5), Ala Val Phe (SEQ ID NO: 6), Phe Val Phe (SEQ ID NO: 7), Ala Phe Ile Gly (SEQ ID NO: 8), Ala Ile Phe Thr (SEQ ID NO: 3), Gly Phe Met

-9-

Thr (SEQ ID NO: 9), Asn Leu Ile Thr (SEQ ID NO: 10), Gln Phe Val Gly (SEQ ID NO: 2), Ser Phe Phe Gly (SEQ ID NO: 11), Ser Phe Val Gly (SEQ ID NO: 12), Asp Phe Phe Val (SEQ ID NO: 13), Asp Phe Phe Val Gly (SEQ ID NO: 1), Lys Leu Val Phe Phe Ala Glu (SEQ ID NO: 14), and Lys Leu Val Phe Phe (SEQ ID NO: 15). Three of the above, SEQ ID NOS: 1, 2 and 3, blocked the amnestic effect of β -(12-28) (26) on retention of FAAT when co-administered to groups of ten mice, each with isomolar amounts (6 nmol) of β -(12-28) (Table 1), giving the following values for trials to criterion \pm SEM and p values for comparison with β -(12-28): β -(12-28) alone, 9.62 ± 0.30 ; with Gln Phe Val Gly (SEQ ID NO: 2), 6.69 ± 0.22 , $p < 0.01$; with Asp Phe Phe Val Gly (SEQ ID NO: 1), 6.80 ± 0.38 , $p < 0.01$; and with Ala Ile Phe Thr (SEQ ID NO: 3), 6.92 ± 0.32 , $p < 0.01$.

-10-

Table 1

Effects of ICV co-administered non-amnestic peptides on amnestic effects of β -(12-28) on retention of FAAT using groups of ten mice

Peptide	Trial to criterion, no (mean \pm SEM) ¹	P-value for comparison with β -(12-28) alone ³
Vehicle alone	6.85 \pm 0.20	-
β -(12-28) alone	9.62 \pm 0.30 ²	-
β -(12-28) + Ala Val Phe	9.31 \pm 0.36	NS ⁴
β -(12-28) + Asp Phe Phe Val	9.31 \pm 0.38	NS
β -(12-28) + Lys Leu Val Phe Phe	9.23 \pm 0.34	NS
β -(12-28) + Asn Leu Ile Thr	9.15 \pm 0.41	NS
β -(12-28) + Lys Leu Val Phe Phe Ala Glu	9.08 \pm 0.30	NS
β -(12-28) + Phe Val Phe	8.92 \pm 0.26	NS
β -(12-28) + Ala Phe Ile Gly	8.92 \pm 0.38	NS
β -(12-28) + Val Val	8.85 \pm 0.42	NS
β -(12-28) + Ser Phe Val Gly	8.85 \pm 0.41	NS
β -(12-28) + Gly Phe Met Thr	8.85 \pm 0.47	NS
β -(12-28) + Phe Phe	8.69 \pm 0.46	NS
β -(12-28) + Ser Phe Phe Gly	8.08 \pm 0.40	NS
β -(12-28) + Ala Ile Phe Thr	6.92 \pm 0.32	<0.01
β -(12-28) + Asp Phe Phe Val Gly	6.80 \pm 0.38	<0.01
β -(12-28) + Gln Phe Val Gly	6.69 \pm 0.22	<0.01

¹ The higher the mean the less the efficacy of a peptide in blocking the amnestic effect of β -(12-28).

² P<0.01 for comparison with vehicle alone.

³ P values were obtained for selected comparisons using Tukey's t-test after obtaining a significant F value by analysis of variance (ANOVA).

⁴ NS = not significant.

-11-

Subsequently Asp Phe Phe Val Gly (SEQ ID NO: 1) and β -(12-28) were given ICV separately post-training before or after saline (2 μ l each, 60 seconds apart) or first Asp Phe Phe Val Gly (SEQ ID NO: 1) and then β -(12-28) or first β -(12-28) and then Asp Phe Phe Val Gly (SEQ ID NO: 1) (Figure 1). Whether saline was given before or after β -(12-28) did not affect the result, indicating that increase of total volume administered ICV from 2 μ l to 4 μ l did not matter. The order of administration of β -(12-28) and Asp Phe Phe Val Gly (SEQ ID NO: 1) did not affect the ability of the latter to block the amnestic effect of the former (Figure 1). These latter results suggest, but do not prove, that direct interaction of the counter-amnestic peptides with β -(12-28) is not the reason for their protective action. Separate experiments with the amnesia blockers Gln Phe Val Gly (SEQ ID NO: 2), Asp Phe Phe Val Gly (SEQ ID NO: 1), and Ala Ile Phe Thr (SEQ ID NO: 3) in weakly trained animals (Table 2) showed these substances not to have any memory-enhancing effects on retention of T-maze FAAT, indicating that amnestic effects of β -(12-28) were not being overcome by independent memory-enhancing effects of these substances.

Table 2

Effects of Asp Phe Phe val Gly (SEQ ID NO: 1), Ala Ile Phe Thr (SEQ ID NO: 3) and Gln Phe Val Gly (SEQ ID NO: 2) on retention of T-maze FAAT measured in weakly trained mice (groups of 14 each)¹

Peptide	Trial to criterion, no (mean \pm SEM)	P-value for comparison with vehicle
Vehicle alone	9.07 \pm 0.25	-
Asp Phe Phe Val Gly	9.14 \pm 0.32	-NS ²
Ala Ile Phe Thr	9.43 \pm 0.30	NS
Gln Phe Val Gly	9.64 \pm 0.28	NS

-12-

1 This paradigm is designed to measure the extent of enhancement, if any, over that found with vehicle alone (0.001% DMSO in saline). None was observed.

2 NS = not significant.

Esters and Amides of Ala Ile Phe Thr (SEQ ID NO: 3), Asp Phe Phe Val Gly (SEQ ID NO: 1) and Gln Phe Val Gly (SEQ ID NO: 2) as Antagonists of Amnestic effects of A β . The most likely additional related substances to synthesize and administer would be esters and amides of the three active peptides (SEQ ID NOS: 1, 2 and 3) in which the carboxyl group of each of them is esterified or amidated.

The peptidic esters preferably have the structural formula:

in which X is a peptide, SEQ ID NO: 1, SEQ ID NO: 2 or SEQ ID NO: 3 and R is a straight or branched chain alkyl group having one to eighteen carbon atoms, an aromatic group, e.g., a substituted or unsubstituted phenyl, naphthyl or anthracyl group, a heterocyclic group, e.g., a pyridine or imidazole group or a steroidal group, e.g., pregnenolone, dehydroepiandrosterone, progesterone or any biologically active steroid having an available hydroxyl group.

The peptidic amides have the structural formula:

in which X may be the same as X in Formula I and in which R₁ and R₂ are the same or different alkyl,

-13-

aromatic, heterocyclic or steroidal group as in Formula I. Such substances may be more resistant to enzymatic attack than the parent peptides and could pass the blood-brain barrier more readily, whereupon they would be hydrolyzed to form the effective peptide in the brain.

CLAIMS:

1. A peptide having the sequence of SEQ ID NO: 1, SEQ ID NO: 2 or SEQ ID NO: 3.
2. A method for antagonizing the amnestic effects of amyloid β protein ($A\beta$) which comprises administering to a mammal affected with the amnestic effects of $A\beta$ a therapeutically effective amount of a peptide having the sequence of SEQ ID NO: 1, SEQ ID NO: 2 or SEQ ID NO: 3.
3. A method as defined by claim 2 in which said peptide is administered orally, subcutaneously, intravenously, transdermally, intranasally, rectally, intrathecally, sublingually, or intracisternally.
4. A method as defined by claim 2 or claim 3 in which said mammal is a mouse.
5. A method as defined by claim 2 or claim 3 in which said mammal is a human.
6. An ester or an amide of a peptide as defined by claim 1.
7. A peptide ester having the structure Formula I.
8. A peptide amide having the structure Formula II.

(54) Title: METHOD OF PREVENTING AGGREGATION OF AMYLOID β -PROTEIN (57) Abstract <p>This invention is directed to methods and compositions for preventing aggregation of amyloid β-protein (βAP) aggregation. Aggregation of amyloid β-protein is associated with the deposition of amyloid in the brain. Amyloid β-protein-binding compounds such as transthyretin are described which form complexes with βAP and prevent formation of amyloid. This invention also identifies the serine 6 mutation in the TTR gene as predictive of person at risk for developing βAP associated amyloidosis.</p>

**METHOD OF PREVENTING AGGREGATION
OF AMYLOID β -PROTEIN**

This invention was made with Government support under Grant NIA 5 RO1 AG0932004 awarded by the National
5 Institute of Health. The Government has certain rights in the invention.

TECHNICAL FIELD OF THE INVENTION

10 This invention relates to methods and compositions useful for preventing aggregation of amyloid β -protein. Aggregation of amyloid β -protein is associated with development of amyloid deposits which are formed in persons with various forms of dementia. This invention
15 also relates to the identification of a genetic marker useful for identifying persons at risk for developing amyloidosis. Accordingly, this invention relates to methods of diagnosing, preventing and treating amyloidosis associated with aggregation of amyloid β -protein.

20 BACKGROUND OF THE INVENTION

The cardinal pathological feature of Alzheimer's disease is the formation of amyloid depositions of aggregated amyloid β -protein (β AP) in the brain and
25 cerebralvasculature. Amyloidosis is a pathologic condition characterized by the deposition of amyloid, a generic term describing abnormal extracellular and/or intracellular deposits of fibrillar proteins. Amyloid deposits may be formed in a variety of tissue and organs
30 including brain, liver, heart, kidney, etc. Advanced amyloidosis may cause extensive tissue breakdown.

Proteins involved in the formation of amyloid have the following common properties: 1) they possess a β -pleated sheet secondary structure; 2) they form insoluble
35 aggregates; 3) they exhibit green birefringence after

- 2 -

° Congo red staining; and 4) they possess a characteristic fibrillar structure when observed under an electron microscopic. Proteins which have been identified as capable of forming amyloid in human disease include:
5 immunoglobulin light chains, protein AA, β_2 -microglobulin, transthyretin, cystatin C variant, gelsolin, procalcitonin, protease resistant protein PrP^{Sc}, and amyloid β -protein.

Amyloid β -protein, or β AP, a polypeptide of 39 to 43 amino acids is a 4-kilodalton derivative of a large
10 transmembrane glycoprotein amyloid β precursor protein (APP). See, D.L. Price, D.R. Borchelt and S.S. Sisodia, *Proc. Natl. Acad. Sci. U.S.A.* **90**, 6381 (1993); Selkoe, D.J. "Amyloid Protein and Alzheimer's Disease", Scientific American, (1991) 265:68 for review. The sequence of
15 amyloid β -protein was determined by Glenner and Wong, *Biochem. Biophys. Res. Comm.* (1984) (120:885) and U.S. Patent 4,666,829 which is incorporated herein by reference. β AP is found in an aggregated, poorly soluble form, in extracellular amyloid depositions in brains and
20 leptomeninges of patients with Alzheimer's disease (AD), Down syndrome (DS), and hereditary cerebral hemorrhage with amyloidosis - Dutch type (HCHWA-D) (D.J. Selkoe, *Neuron* **6**, 487 (1991); D.L. Price, D.R. Borchelt and S.S. Sisodia, *Proc. Natl. Acad. Sci. U.S.A.* **90**, 6381 (1993)).
25 In contrast, β AP has been detected in a soluble form in cerebral spinal fluid (CSF) and plasma of healthy individuals and patients with AD. Seubert, P. et al. Nature (1992), 359:325.

A number of studies of synthetic β AP *in vitro* have
30 shown that β AP aggregates easily and forms amyloid fibrils similar to the fibrils found in brains of patients with AD and DS (E.M. Castano et al., *Biochem. Biophys. Res. Commun.* **141**, 782 (1986); D. Burdick et al., *J. Biol. Chem.* **267**, 546 (1992); J.T. Jarrett and P.T. Lansbury, Jr.,
35 *Cell*, **73**, 1055 (1993)). The mechanism by which this

- 3 -

normally produced peptide forms amyloid is unknown. It has also been unknown why β AP, in a soluble form, is present in biological fluids of healthy individuals and patients with AD.

Recently, several extracellular proteins have been identified that bind immobilized β AP. These include apoE, apoJ, and APP, all of which are found in CSF (W.J. Strittmatter et al., *Proc. Natl. Acad. Sci. U.S.A.* **90**, 8098 (1993); J. Ghiso et al., *Biochem. J.* **293**, 27 (1993); W.J. Strittmatter et al., *Experimental Neurology* **122**, 327 (1993)). The binding of apoE, the major CSF apolipoprotein which exists in 3 major isoforms, is particularly relevant to late-onset familial and sporadic AD. Patients homozygous for the apoE4 isoform have more amyloid depositions than patients homozygous for the apoE3 isoform (W.J. Strittmatter et al., *Proc. Natl. Acad. Sci. U.S.A.* (1993), 90:1977). The inheritance of the APOE4 allele also significantly increases the risk and decreases the age of onset of AD (E.H. Corder et al., *Science* **261**, 921 (1993)). Although, apoE appears to be a candidate for sequestration of β AP, it was unknown as to whether apoE bound β AP and formed complexes *in vivo*.

Transthyretin (TTR), also referred to as prealbumin, is a homotetrameric, protein each subunit of which contains 127 amino acids. Its secondary, tertiary and quaternary structure has been described Blake et al. in *J. Mol. Biol.* (1978) 121:339, which is incorporated herein by reference. The TTR tetramer has a molecular weight of about 54,980 daltons. TTR is synthesized in liver and the chorioid plexus and is present in the serum and cerebral spinal fluid (CSF). In human CSF, TTR is usually present at a concentration of about 0.3 micromolar. Only albumin which is present in a concentration of about 2 micromolar is present in CSF at a higher concentration. TTR is known to be the main carrier of thyroxine and vitamin A across the blood brain barrier. The presence of TTR in amyloid

- 4 -

deposits associated with AD and Down's syndrome has been suggested by Shirahama, T. et al. Am. J. Pathol. (1982), 107:041, but not confirmed. Eikelenboom, P. and F.C. Stam, Virchows Arch. [Cell P.] (1984), 47:17.

5 TTR which forms amyloid deposits in patients with certain familial amyloid polyneuropathy's (FAP's) has been determined to have various amino acid substitutions compared to circulating transthyretin of normal individuals. For example, a substitution of a methionine for valine at amino acid residue number 30 has been
10 identified in kinships of Portuguese (Saraiva, M.J.M. et al., *J. Clin. Invest* (1984) 74:104), Japanese (Tawara, S. et al., *Biochem. Biophys. Res. Comm.* (1983) 116:880) and Swedish ancestry (Dwulet, et al., *Proc Natl. Acad. Sci. USA* (1984) 81:694; and Whitehead, A.S. et al., *Mol. Biol. Med.* (1985) Vol. 7). In another form of FAP disease, the
15 TTR protein present in the affected individuals has serine substituted for isoleucine at position 84. Wallace et al., *Clin. Res.* (1985) (33:592A). Studies of TTR levels in AD patients and patients with Down syndrome report that
20 TTR concentrations may be decreased in these patients. Riisoe, H., *Acta Neurol. Scand.* (1988) 78:455 and Elovaara, I. et al., *Acta Neurol. Scand.* (1986) 74:245.

Sipe et al., United States Patent 4,186,388 refers to the cloning of the human TTR gene and its use to identify
25 various forms of FAP's. Use of the gene and specific cDNA fragments capable of hybridizing with DNA fragments of biological samples is reported to be useful to identify individuals with various forms of FAP disease including type I FAP disease in which methionine is substituted for
30 valine at position 30 as described above. Sipe et al. report that TTR is associated with amyloid deposits in Alzheimers disease, FAP, and senile cardiac amyloidosis. Sipe et al., further state that the function of TTR in the
35 nervous system is unknown.

- 5 -

Chromosomal localization of genes causing AD can facilitate early diagnosis of persons with this disease. Prenatal diagnosis in affected families is also possible once a genetic marker for a disease is identified. Subsequent delineation of closely linked markers which show strong linkage disequilibrium with the disorder and ultimately, identification of the defective gene can allow screening of the entire at-risk population to identify carriers, begin early prophylactic or therapeutic intervention if available and potentially reduce the incidence of new cases.

There is a need for effective methods and compositions for preventing aggregation of β AP and of identifying individuals at risk for developing amyloidosis.

SUMMARY OF THE INVENTION

This invention provides methods and compositions useful for preventing aggregation of amyloid β -protein. The methods are useful for preventing aggregation of amyloid β -protein (β AP) *in vivo* and *in vitro* and therefore, may be used to prevent or treat mammals, especially humans with amyloidosis associated with β AP aggregation. The methods are also useful for diagnosing persons at risk for developing amyloidosis associated with amyloid β -protein aggregation.

The compositions of this invention promote complex formation between β AP and β AP-binding compounds such as TTR, which are capable of complexing with β AP, in a manner which prevents β AP from self-aggregating and forming amyloid.

The method of preventing aggregation of β AP according to this invention comprises providing a β AP-binding compound to a fluid or biological tissue comprising β AP. The β AP-binding compound is provided in an amount sufficient

- 6 -

to sequester β AP in complexes comprising β AP and the β AP-binding compound so that β AP is not available to self-aggregate.

By preventing β AP aggregation and amyloid deposition, this invention also provides methods and compositions
5 useful for preventing and treating diseases associated with β AP amyloid formation, including, for example, AD, Down's Syndrome and hereditary cerebral hemorrhage with amyloidosis - Dutch type.

This invention also provides assays for detecting β AP
10 or TTR in a biological fluid based on the formation of complexes comprising β AP and at least one β AP-binding compound.

Also provided is a method of detecting persons at risk for developing β AP associated amyloidosis by
15 identifying the presence of a mutation in the TTR gene. The mutation involves a G-A transition in codon 6 resulting in the substitution of serine at amino acid position 6 for the normally present glycine. Because this mutation also creates a BsrI restriction site, this
20 invention also provides a method of identifying persons at risk for developing β AP amyloidosis. The method comprises obtaining DNA from a person; amplifying the gene, or portion thereof, comprising the codon for the sixth amino acid (glycine) of TTR; digesting the amplified DNA with a
25 restriction enzyme such as BsrI; and analyzing the fragments for the presence of an alteration in restriction fragments compared to controls to detect the Serine 6 mutation.

It is an object to this invention to provide methods
30 of preventing aggregation of β AP in solution by sequestering β AP in complexes with β AP-binding compounds such as TTR. Prevention of aggregation is useful for preventing fibril and amyloid formation associated with disease.

35

- 7 -

Another object of this invention is to provide compositions useful for complexing with β AP to so as to sequester β AP preventing β AP from forming aggregates.

It is another object to this invention to provide assays suitable for determining the amount of β AP or TTR in a biological fluid.

Another object of this invention is to provide methods and compositions useful for genetic screening of individuals to identify individuals who have a mutation in the TTR gene and who may be at risk for developing β AP associated amyloidosis.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1. Analysis of ^{125}I - β complexes with CSF proteins. $10\mu\text{l}$ CSF were incubated with 10^5 dpm ^{125}I - βAP_{1-28} (specific activity $3-6 \times 10^6$ dpm/ μg) in a final volume of $20\mu\text{l}$ PBS, Ph 7.4 at 37°C for 8 hours, except an experiment illustrated in Figure 1a. The complexes were analyzed by electrophoresis in a 12% SDS-polyacrylamide gel under non-reducing conditions except for an experiment illustrated in figure 1g, lane 2.

°

DETAILED DESCRIPTION OF THE INVENTION

This invention describes methods and compositions useful for preventing aggregation of soluble amyloid β -protein. We have determined that β AP present in cerebral spinal fluid (CSF) is predominantly bound to TTR. In addition, we have identified a unique binding interaction between TTR and β AP in biological fluids. In another embodiment of this invention a mutation in the gene encoding transthyretin has been identified in patients with AD, the presence of which is highly predictive of patients at risk for developing AD and is also useful for diagnosing persons with AD.

This invention provides compounds useful for preventing aggregation of β AP in solution. We have identified that β AP which normally self-aggregates when in solution, may be prevented from self-aggregating by causing the β AP to form a complex with β AP-binding compounds (BBC's). For the purposes of this invention, BBC's are any compound which form a complex with β AP and which prevent β AP aggregation and formation of amyloid. Examples of BBC's for use with this invention include, but are not limited to, TTR, TTR analogs, and apoE.

The identification of the ability of BBC's to prevent aggregation of β AP, and subsequent amyloid formation, provides for methods of diagnosing, preventing, and treating persons with, or at risk for developing amyloidosis resulting from β AP aggregation.

Binding of a BBC to β AP occurs at physiologically relevant concentrations. For example, TTR which is normally present in CSF at a concentration of about 300 nM may be caused to bind to β AP present in a solution at concentrations of about 3 nM, which is similar to β AP's concentration in CSF.

By assessing the binding interaction between a BBC, such as for example TTR, and β AP in an appropriate fluid

- 11 -

or biological tissue including CSF, one can monitor the extent of BBC- β AP complex formation. Such monitoring of BBC- β AP complex formation may be done in the context of a diagnostic test to determine whether the normal BBC- β AP binding phenomenon is altered.

Alterations in BBC- β AP complex formation *in vivo* resulting from either alterations in BBC's or β AP may result in increased amounts of free β AP available to aggregate and form amyloid. Changes in the amino acid sequence of BBC's or β AP, or in their rate of synthesis or degradation may result in a decrease in complex formation resulting in β AP aggregation. Such alterations would put a person at risk for developing amyloid deposits resulting from β AP aggregation.

We have determined that TTR is the predominant BBC in CSF which is responsible for preventing β AP from aggregating and forming amyloid. In CSF, TTR binds with β AP to form a complex which sequesters β AP and prevents β AP from self-aggregating. Because TTR is the predominant BBC in CSF, to determine if someone is at risk for developing amyloidosis resulting from β AP aggregation, it would be preferable to monitor the binding interaction between β AP and TTR. Binding of TTR to β AP may also be monitored to determine the effectiveness of a treatment directed at sequestering β AP or reducing the concentration of β AP available for aggregation. Measuring TTR- β AP binding interactions may also be used to identify other BBC's which are also suitable for complexing to β AP in a manner which sequesters β AP so that it is unavailable to aggregate and form amyloid depositions.

Binding of BBC to β AP may be measured by using standard binding assays known to those skilled in the art, based on the teachings disclosed herein. For example, β AP and TTR may be allowed to form complexes in solution. Detection of the complexes may be accomplished using chromatographic techniques, for example, molecular sieve

- 12 -

exclusion chromatography. SDS-PAGE electrophoresis may also be used.

Assays involving immobilization of either β AP or TTR to a solid support may also be used to detect binding of the corresponding partner (i.e., TTR if β AP is immobilized). The method of Strittmatter, W. et al., *Proc. Natl. Acad. Sci., USA* (1993), 90:1977 which is incorporated herein by reference, for binding apolipoprotein (APOE) to β AP, may be used to demonstrate complex formation between TTR and β AP. Detection of bound TTR or β AP may be accomplished by methods well known in the art including use of enzymatic or radioactive labels.

Binding of human TTR to β AP is specific. Evidence of specific binding between TTR and β AP may be provided using a competition assay. In such an assay, either one of β AP or TTR is labelled in a binding assay as described above. An excess of unlabelled ligand of the same type which is labelled (i.e., excess of β AP if labelled β AP is used) is included in the reaction mixture to compete with and prevent binding of the labelled ligand. Preferably, the unlabelled ligand will be present in the reaction mixture in excess of between 100 to 1000 times the concentration of the labelled ligand.

BBC's which are useful with this invention prevent the aggregation of β AP and subsequent amyloid formation. The inhibition by a BBC of one or more properties of amyloid, would be indicative of a BBC useful with this invention. These properties of amyloid include, for example, the ability of a BBC to 1) prevent β AP from assuming a β -sheet secondary structure, 2) prevent β AP from aggregating to form an insoluble structure, 3) inhibit β AP from forming structures which exhibit green birefringence after Congo red staining, and 4) prevent β AP from forming fibrils with typical electron microscopic appearance. TTR, which is a preferred BBC for use with

- 13 -

° this invention, prevents amyloid formation according to all four criteria.

We used computer modeling of the binding interaction between β AP and TTR to identify the specific molecular surfaces of β AP and TTR which participate in complex
5 formation. The identification of the amino acid sequences of TTR and β AP relevant to the binding interaction allows for the synthesis of other BBC's including polypeptides, analogs of TTR and other molecules which would bind to β AP to prevent its aggregation. Analogs of TTR include
10 fragments of TTR, and TTR having amino acid substitutions, deletions, or additions as well as other molecules that share a similar TTR binding domain which is important for preventing amyloid formation. The TTR analogs form complexes with β AP to prevent its aggregation and amyloid
15 formation. In addition, unless otherwise specifically stated, reference herein to TTR is meant to include TTR analogs as well. Based on the teachings disclosed herein, other types of molecules may also be capable of binding to β AP to prevent its aggregation. Such molecules include
20 organic molecules such as for example Buckminsterfullerenes. Preferably, BBC's and TTR analogs bind to β AP at concentrations which avoid harmful side effects in an individual to whom they may be administered.

The TTR analogs may include analogs of TTR in which
25 the amino acid sequence of human TTR is substituted with amino acids which allow for the TTR- β AP binding interaction to occur. Such substitutions include substituting neutral amino acids such as glycine, alanine, valine, leucine and isoleucine for other neutral amino
30 acids present in the TTR sequence. In addition, substitution of aromatic amino acids present in TTR may be accomplished using phenylalanine, tyrosine or tryptophan. Aliphatic amino acids in TTR possessing hydroxyl groups may be substituted with serine or threonine. Amino acids
35 present in TTR having basic side chains may be substituted

- 14 -

° with lysine, arginine, and histidine, whereas amino acids having acidic side chains may be substituted with aspartic acid or glutamic acid. Asparagine may be substituted for glutamine which both have amide chains.

5 Because of a large contact surface between β AP and TTR it may be possible that not all amino acid substitutions be a precise one-to-one equivalency. Some flexibility of the choices may be necessary, as long as the analog attempts to reproduce with reasonable fidelity the shape of the TTR binding surface and the engendered
10 electrostatic potential mimics that of TTR within a reasonable range. More precisely the $-1kT$ electrostatic potential contour of the analog should cover essentially the same area as in TTR and its location should not be closer than about a 2\AA displacement toward the surface, as
15 compared with the TTR potential contour.

Without being bound by theory, the portion of the amino acid sequence of TTR which participates in the binding with β AP extends from about amino acid residue 30 to 70. Within this amino acid sequence, the specific
20 amino acids of TTR comprising Arg (34, 161), Ala (37, 164), Asp (38, 165), Thr (40, 167), Glu (42, 169), Glu, (62, 189), Val (65, 192), and Glu (66, 193) are preferred. (The first number is the order number at the first residue on chains 1 and 3; the second number refers to the residue
25 in chains 3 and 4.)

According to the model, negative amino acid residues Asp (38, 165), Glu (42, 169), Glu (62, 189), and Glu (66, 193) present on the essentially convex surface of TTR comprising by all the amino acids specified in the
30 preceding paragraph are responsible for generating a negative electrostatic potential around that specific region of TTR so as to specifically interact with the positive electrostatic potential engendered by specific positive amino acids on the surface of the β AP. These
35 positive amino acids of β AP, which are located in an

- 15 -

essentially concave surface which specifically interacts with TTR to form the complex include Arg (5), His (13), Lys (16), and Lys (28). These positive amino acids on β AP reside in the essentially concave larger contacting surface of β AP referred to above comprising amino acid residues Arg (5), Ser (8), Gly (9), Val (12), His (13), Gln (15), Lys (16), Phe (19), Phe (20), Asp (23), Val (24), Asn (27), and Lys (28).

The most important parameters for describing the binding interaction between TTR and β AP are the detailed curvatures of the surface and the electrostatic potentials generated by the charged amino acids. The contacting surfaces of TTR and β AP are the surfaces described by the listing of the specific amino acid residues in TTR and β AP listed above. The negative electrostatic potential on TTR is engendered by the negative amino acids listed above, and similarly, the positive amino acids on β AP engender the positive potential around its surface.

This invention includes other BBC's which bind to the TTR binding site of β AP, or portions thereof, and which prevent the aggregation of β AP and formation of amyloid. In addition, compounds which alter the TTR binding site of β AP, whether or not they bind to this site, but bind to β AP and prevent its aggregation are contemplated as well. Also, compounds that possess a surface shape and electrical change similar to the binding site of TTR or part thereof, could prevent β AP aggregation and amyloid formation and are contemplated as well.

This invention provides a method of preventing aggregation of soluble β AP present in a solution at a given concentration. β AP may be present in solutions *in vitro* or *in vivo*. Biological tissues in which β AP is present include CSF, cerebralvasculature, or brain. To prevent aggregation of β AP, a sufficient amount of TTR or TTR analog is provided to the β AP containing solution or tissue to form TTR- β AP complexes. As shown in Fig. 6,

- 16 -

° evidence of inhibition of aggregation may be demonstrated by the inhibition of β AP-fibril formation.

Inhibition of β AP may be accomplished over a wide BBC to β AP ratio. In CSF of normal individuals in which β AP is not aggregated, TTR is present at a concentration of
5 about 300 nM, whereas β AP is present at about only 3 nM. Accordingly, a suitable ratio of TTR to β AP for use with this invention is about 100 to 1. However, *in vitro*, we have determined that TTR, at about 1.2 μ M, prevents about
10 50% of aggregation of β AP present at about 300 μ M. Fig. 4. Therefore, a ratio of BBC to β AP of about 1 to 100 is also preferred for use with this invention. In addition, a ratio of BBC to β AP of about 1 to 4 is also preferred based on the stoichiometry of the β AP and TTR binding.
15 BBC to β AP ratios of 1 to 2 and 1 to 1 are also preferred. These ratios may be optimized for use with BBC's besides TTR.

As the concentration of TTR is increased, the formation of β AP aggregates having a high molecular weight decreases. Fig. 4(b). Because as little as about 3 μ M TTR
20 can essentially completely inhibit aggregate formation of about 300 μ M β AP, it is likely that TTR also inhibits aggregation of β AP by mechanisms other than by the simple stoichiometric model discussed above. Accordingly, the administration of BBC's such as TTR would be useful to
25 prevent the enlargement of amyloid deposits existing prior to initiation of treatment.

Endogenous TTR present *in vitro* or *in vivo*, which is capable of binding to β AP at the TTR binding site in a manner which prevents β AP aggregation, for the purpose of
30 this invention is considered to contribute to the total amount of TTR or TTR analog in determining the ratios described above. In situations where endogenous TTR is mutated or is in a form which does not effectively prevent β AP aggregation, then the amount of exogenous TTR, or TTR
35 analog, added to the solution would be an amount

- 17 -

° sufficient to inhibit β AP aggregation independent of the endogenous TTR and preferably would be an amount to achieve one of the ratios described above.

5 The TTR- β AP binding interaction described according to the invention is also useful in assays to determine the amount of β AP or TTR in a biological sample. Several protocols known in the art including immunoassay and receptor binding assays may be adapted to take advantage of the complex formation formed between β AP and TTR. For example, according to one embodiment of this invention, an
10 assay to determine the amount of soluble β AP present in a sample would comprise the steps of combining the sample with a soluble or bound BBC, such as TTR, in the presence of a known amount of soluble labelled β AP and detecting the amount of β AP in the sample. According to a preferred
15 embodiment, TTR is bound to a solid support.

In another embodiment of the assay, a sample containing an unknown amount of TTR or mutated form of TTR may be combined with β AP bound to a solid support. Labeled TTR may then be added to the sample to determine
20 by competition the amount of endogenous TTR or mutated TTR present in the sample.

Other assay protocols including sandwich assays are contemplated by this invention. For example, to measure β AP in a sample, TTR may be linked to an insoluble support to which is added the sample containing the unknown amount
25 of β AP. Anti- β AP-antibody which is labeled may then be added to the sample to detect the amount of bound β AP. Such an assay may also be constructed to determine the amount of TTR in a sample.

30 In another embodiment of the invention, soluble β AP *in vivo* is prevented from aggregating by providing a BBC to form complexes with β AP *in vivo*. The BBC, preferably TTR, is provided in an amount sufficient to complex with soluble β AP so as to reduce the concentration of free β AP
35 in solution. Reduction of soluble β AP and the formation

- 18 -

of BBC- β AP complexes sequesters the β AP and decreases the amount of β AP available for forming aggregates and amyloid deposition. Inhibition of β AP aggregation and amyloid formation is useful from the prevention or treatment of Alzheimer's Disease, Down's Syndrome and hereditary cerebral hemorrhage with amyloidosis - Dutch type.

The methods and compositions of this invention are also suitable for use with mammals besides humans such as monkeys, dogs and any other mammal that develops β AP amyloidosis. (D.J. Selkoe, *Neuron* 6, 487 (1991)).

This invention also provides a method of identifying persons at risk for developing amyloidosis based on the identification of a mutation in the TTR gene involving a substitution of serine for glycine at position 6 of TTR. This substitution arises from a single point mutation in which the first guanine in the GGT codon is substituted with an adenine to produce the AGT codon. A study by Jacobsen et al. "Transthyretin ser 6 gene frequency in individuals without amyloidosis", VII International Symposium on Amyloidosis, July 11-15, 1993, 100, which is incorporated herein by reference, reports that the serine 6 gene is a common normal TTR polymorphism present at a frequency of about 12 % and, "apparently not associated with amyloidosis in the Caucasian population." We have surprisingly found that in a population of 55 unrelated AD patients, 10 (i.e. 18 %) were heterozygous for this serine 6 mutation. As AD is believed to be a heterogenous disorder arising from a variety of causes, this result is consistent with the serine 6 mutation identifying a subpopulation of AD patients. This mutation was found in 7 families with patients with late onset of AD disease.

To identify persons at risk of developing AD associated with the serine 6 mutation, the DNA containing the second exon encoding TTR may be sequenced by methods known to those skilled in the art, or the DNA may be analyzed using restriction enzymes which can identify a

- 19 -

change in the recognition site for the restriction enzyme. The substitution of A for G, destroys an MspI site and creates a BsrI site. The methods described in Sipe et al. U.S. patent 4,816,388, which is incorporated herein by reference, may also be modified to identify the serine 6 mutation.

In one method, PCR-SSCP analysis as described by Orita et al., Genomic, (1989), 5:874-879, which is incorporated herein by reference, is performed to identify the serine 6 mutation. Using PCR, primers which amplify the second exon of TTR may be used to amplify the region of the gene containing the serine 6 mutation. PCR may be performed using methods described in Mullis et al. U.S. patent 4,683,195, which is incorporated herein by reference. The following oligonucleotide probes are suitable for amplifying the appropriate region of exon 2 of TTR:

5' CGC TCC AGA TTT CTA ATA CCAC 3' (1515-1537)

5' AGT GAG GGG CAA ACG GGA AGAT 3' (1791-1769)

(The number in parenthesis represents the positions of the bases in the TTR gene.)

Following amplification of the gene fragment, the fragment may be sequenced or treated with restriction enzymes to determine whether the serine 6 mutation is present. Following separation of the amplified DNA fragment from the genomic DNA, the amplified fragment may be digested with BsrI to determine if this restriction site is present.

The identification of a marker associated with a form of AD lends itself to the formulation of kits which can be utilized in diagnosis. Such a kit may comprise a carrier being compartmentalized to receive in close confinement one or more containers wherein a first container may contain oligonucleotides for amplifying the appropriate region of the genomic DNA. Other containers may contain reagents, such as restriction enzymes or labelled probes,

- 20 -

°
useful in the detection of the mutation. Still other containers may contain buffers and the like.

BBC's such as TTR, and in particular, analogs suitable for use in this invention, may be produced by means known in the art including linking of individual
5 amino acids to construct specific sequences, modification of purified TTR or by recombinant techniques. Recombinant production of TTR is described in Sipe et al., United States Patent No. 4,816,388 which is incorporated herein by reference. To produce TTR analogs, cDNA encoding TTR
10 may be modified to contain coding sequences coding for the desired TTR analog. Standard synthetic chemical techniques may be used for producing other BBC's.

To provide treatment, or prevent amyloidosis associated with β AP aggregation, BBC's such as TTR, should
15 be administered to the individual in need of treatment in a therapeutically effective amount. Preferably, the BBC should be administered to the individual in an amount sufficient to achieve a concentration *in vivo* sufficient to prevent aggregation of β AP.

20 BBC's such as TTR, which are to be administered according to this invention may be administered as a pharmaceutical composition further comprising a biologically acceptable carrier including, but not limited to, saline, buffer, dextrose and water.

25 BBC's such as TTR may be administered by known methods including, sublingual, intravenous, intraperitoneal, percutaneous or intranasal modes of administration. Local administration directly to the site of action may also be desirable and may be accomplished
30 through means known in the art including, but not limited to, injection, infusion and implantation of infusion devices containing the BBC. Similarly to administration of other peptides, administration is preferably by means which avoid contact with the gastrointestinal tract. The
35 administration of a BBC such as TTR directly to the CSF

- 21 -

may be accomplished by intrathecal injection. In a preferred method of the invention, BBC, and in particular TTR, is provided to the individual in need of treatment by inducing its endogenous production in the individual in need of treatment.

5 In another embodiment of the invention, a BBC such as TTR may be provided to an individual through gene therapy. To provide gene therapy to an individual, specific DNA sequences which code and express a desired protein are inserted into an appropriate vector complex which is then
10 used to infect an individual in need of treatment. Various methods and vectors may be used for introducing a desired genetic sequence into an individual. The preferred and most often used method, incorporates the desired genetic sequence, for example a cDNA encoding TTR,
15 into the genome of a retrovirus to form chimeric genetic material. The genetically altered retrovirus may then be used to infect the appropriate target cells *in vitro* or *in vivo*. Preferably, the retrovirus is altered so the desired sequences are inserted into the genome of the
20 target host cells and replicated without replicating the infecting virus. The result of a successful gene transfer via a retrovirus vector is a virally infected host cell which expresses only the desired gene product. For reviews on gene therapy using retroviral vectors see WO
25 92/07943 published May 14, 1992 "Retroviral Vectors Useful for Gene Therapy" and Richard C. Mulligan, "Gene Transfer and Gene Therapy: Principle, Prospects and Perspective" in *Etiology of Human Disease at the DNA Level*, Chapter 12. Jan Linsten and Alf Peterson, eds. Rover Press, 1991,
30 which are incorporated herein by reference. Additional viral vectors suitable for providing gene sequences include but are not limited to adeno-associated viruses, Herpes Simplex 1 Virus and vaccinia.

35 The biological activity of BAP has been demonstrated in a number of experiments (1, 16). Binding of TTR and

- 22 -

other proteins to β AP may regulate its biological activity and play a role in the transport of the peptide.

The identification of β AP binding proteins suggests that prevention of β AP aggregation and amyloid formation requires a dynamic equilibrium of multiple extracellular factors participating in the sequestration of β AP. A decreased level of TTR in CSF (H. Riisøen, *Acta Neurol. Scand.* **78**, 455 (1988); I. Elovaara, C.P.J. Maury, J. Palo, *Acta Neurol. Scand.* **74**, 245 (1986)) and an increased expression of apoE, apoJ, and APP in the brains of AD patients (J.F. Diedrich et al., *J. Virol.* **65**, 4759 (1991); D.L. Price, D.R. Borchelt and S.S. Sisodia, *Proc. Natl. Acad. Sci. U.S.A.* **90**, 6381 (1993)). P.C. May et al., *Neuron* **5**, 831 (1990) could alter the existing equilibrium and facilitate amyloid formation. Subtle differences, such as the single amino-acid substitution previously demonstrated for two apoE isoforms, may significantly influence the amount of amyloid formed in AD brains (D.E. Schmechel et al., *Proc. Natl. Acad. Sci. U.S.A.* (1993), 90:9649-9653). Over thirty mutations have been documented in TTR, and some lead to TTR amyloid formation in familial amyloidotic polyneuropathy (M.D. Benson and M.R. Wallace in *The Metabolic Basis of Inherited Disease*, C.R. Scriver, A.L. Beudet, W.S. Sly and D. Valle Eds. (McGraw-Hill Book Co., New York, 1989), pp. 2439-2460; D.R. Jacobson and J.N. Buxbaum in *Advances in Human Genetics* Vol. 20, H. Harris and K. Hirschhorn Eds. (Plenum Press, New York, 1991), pp. 69-123). Variants of TTR could be associated with AD in families not linked to other defined genetic loci on chromosomes 14, 19 and 21 (D.J. Selkoe, *Neuron* **6**, 487 (1991); D.L. Price, D.R. Borchelt and S.S. Sisodia, *Proc. Natl. Acad. Sci. U.S.A.* **90**, 6381 (1993); E.M. Castano and B. Frangione, *Lab. Invest.* **58**, 122 (1988)) or modulate the effect of the defined loci. The suggested structure of TTR- β AP complex, furthermore, provides a

- 23 -

° molecular basis for the design of drugs to prevent amyloid formation.

EXAMPLES

Example 1

5

A. To identify the proteins interacting with β AP in human CSF, synthetic β AP₁₋₂₈ and β AP₁₋₄₀ labeled by an iodinated Bolton-Hunter reagent were used.

10

Synthetic β AP₁₋₂₈ and β AP₁₋₄₀ from Bachem were radioiodinated using ¹²⁵I Bolton-Hunter reagent from Amersham according to manufacturer's instructions. Ten microliters of human CSF were incubated with 10⁵ dpm ¹²⁵I- β AP₁₋₂₈ (specific activity 3-6 x 10⁶ dpm/ μ g) in a final volume 20 μ l PBS, pH 7.4 at 37°C hours. Incubation under 15 five (5) different conditions (A, B, C, D and E) were conducted to analyze complex formation of β AP. The incubation conditions were as follows:

(A) ¹²⁵I- β AP₁₋₂₈ was incubated for 24 hours in PBS (Fig. 2(a), lane 1). ¹²⁵I- β AP₁₋₂₈ was incubated for 24 hours 20 in PBS, centrifuged through 20% sucrose cushion at 15000xg for 10 minutes and the pellet was analyzed by SDS-PAGE (Fig. 2(a), lane 2).

(B) Complexes of ¹²⁵I- β AP₁₋₂₈ with CSF proteins formed after incubation for 24 hours (Fig. 2(b), lane 1) or 10 25 minutes (Fig. 2(b), lane 2). Complexes of ¹²⁵I- β AP₁₋₂₈ with human apoE3 formed after incubation for 24 hours (Fig. 2(b), lane 3).

(C) Competition of complex formation of ¹²⁵I- β AP₁₋₂₈ with CSF proteins by unlabeled β AP₁₋₂₈. Radiolabeled β AP was incubated with CSF (Fig. 1(d), lane 1), with CSF and 10 fold excess of unlabeled β AP₁₋₂₈ (Fig. 1(d), lane 2), 30 with CSF and 200 fold excess of unlabeled β AP₁₋₂₈. A triangle indicates a 30 kDa band.

(D) Competition of complex formation of ¹²⁵I- β AP₁₋₂₈ 35 with TTR (Calbiochem) by unlabeled β AP₁₋₄₀. Radiolabeled

- 24 -

° BAP was incubated with 0.1 μ M TTR (Fig. 1(f), lane 1), 0.1 μ M TTR and 100 fold excess of unlabeled β AP₁₋₄₀ (lane 2), 0.1 μ M TTR and 500 fold excess of unlabeled β AP₁₋₄₀ (lane 3).

5 (E) Effect of boiling in SDS under reducing conditions on TTR- β AP complexes. 125 I- β AP₁₋₂₈ was incubated with 0.1 μ M TTR and before electrophoresis was incubated in 50 mM tris-HCL, pH 6.8 for 5 minutes at room temperature (Fig. 1, lane 1), or was boiled for 10 minutes in 50 mM tris-HCL, pH 6.8, 2% SDS and 0.2 M β -
10 mercaptoethanol (Fig. 1(g), lane 2).

Samples were mixed 1:1 with 2x loading buffer 100 mM tris-HCL, pH 6.8 and analyzed by 13% tris-tricine SDS-PAGE (A) or by 12% tris-glycine SDS-PAGE (B, C, D, E). The
15 gels were dried and exposed to an X-ray X-Omat film from Kodak.

Time course experiments of complex formation demonstrated rapid formation of TTR- β AP complexes (Figs. 1 b and c) even in the presence of ApoE3 (Fig. 1(c)).

20 The experiments were repeated with 125 I- β AP₁₋₂₈, and the same results were obtained.

When radiolabeled β AP₁₋₂₈ or β AP₁₋₄₀ was added to CSF samples, instead of aggregates, two bands with apparent molecular weights of 30 and 50 kDa were observed (Fig. 1b). These bands were distinct from the 40 kDa apoE- β AP
25 complexes (Fig. 1b, lane 3) that were previously described (W.J. Strittmatter et al., *Proc. Natl. Acad. Sci. U.S.A.* 90, 8098 (1993); J. Ghiso et al., *Biochem. J.* 293, 27 (1993); W.J. Strittmatter et al., *Experimental Neurology* 122, 327 (1993)). The formation of radiolabeled β AP
30 complexes in CSF could be specifically competed with unlabeled β AP (Fig. 1(d), lane 3).

B. The CSF protein that formed a 30 kDa complex with β AP was purified, subjected to trypsin digestion, and the two largest peptides were sequenced.
35

- 25 -

o The purification of β AP binding activity was monitored using ^{125}I - βAP_{1-28} and SDS-PAGE and included three steps. Step 1: Chromatography of 5 ml CSF on a DEAE column and elution with a step-gradient in 50 mM tris-HCl, pH 7.4. The peak of binding activity was eluted at 0.4 M NaCl. Step 2: The peak fractions were combined, diluted five times and further passed through a heparin-sepharose column in 50 mM NaCl, 50 mM tris-HCl pH 7.4. The β AP binding activity appeared in unbound fractions. Step 3: The combined fractions containing β AP binding activity were chromatographed on a FPLC-mono Q column with a gradient 0.1 - 0.3 M NaCl in 50 mM tris-HCl, pH 7.4. Fractions with peak activity from several experiments were combined, and 200 μg of purified protein were concentrated on a Speed Vac concentrator, reduced and alkylated. The protein was digested with trypsin and separated by reverse phase HPLC. The two largest peptides were sequenced by automated Edman degradation with an Applied Biosystems 477A sequencer with online PTH analysis using an Applied Biosystems 120A HPLC. The result of sequence analysis identified the sequences as **ALGISPFHEHAEVVFTANDSGP** and **RYTIAALLSPYSYSTTAVVTNPK**.

C. The identified amino acid sequences of the two largest peptide sequences perfectly matched amino-acid residues 81 to 102 and 104 to 127, respectively, of transthyretin (TTR), a transporter of thyroxine and vitamin A in the brain (M.D. Benson and M.R. Wallace in *The Metabolic Basis of Inherited Disease*, C.R. Scriver, A.L. Beudet, W.S. Sly and D. Valle Eds. (McGraw-Hill Book Co., New York, 1989), pp. 2439-2460; D.R. Jacobson and J.N. Buxbaum in *Advances in Human Genetics* Vol. 20, H. Harris and K. Hirschhorn Eds. (Plenum Press, New York, 1991), pp. 69-123)). Commercial human plasma TTR also formed 30 kDa complexes with βAP_{1-28} that could be competed with unlabeled βAP_{1-40} demonstrating specificity of binding (Fig. 1(f), lane 3. TTR is a homotetrameric protein with

- 26 -

127 amino-acid residues in each chain, which dissociates to form 30 kDa dimers in SDS, and 15 kDa monomers after boiling in SDS with reducing agents (R. Murrell et al., *J. Biol. Chem.* **267** 16595 (1992)). The 30 kDa TTR- β AP complexes appeared as 15 kDa complexes after boiling in SDS with reducing agents, suggesting that TTR monomer binds β AP (Fig. 1(g)). Using similar analytical techniques, we identified the CSF protein that formed the 50 kDa complex with radiolabeled β AP as albumin.

10 Example 2

We determined that TTR is the major β AP binding protein in CSF. Unlabeled β AP was incubated with CSF, TTR or bovine serum albumin, and the complexes were analyzed using Western blot techniques with anti-TTR and anti- β AP antibodies. Ten microgram of β AP₁₄₀ was incubated in 40 μ l samples overnight at 37°C in PBS, pH 7.2 with either 10 μ g CSF (Fig. 3(a), lane 1), 1 μ g TTR (lane 2), or 50 μ g BSA (lane 3). Controls consisted of ten microliters CSF (lane 4) or one microgram TTR (lane 5) in 40 μ l PBS, pH 7.2 without β AP. The samples were analyzed by SDS-PAGE and immunoblotting using rabbit anti- β AP antibody SGY2134 kindly provided by Steven G. Younkin from Case Western Reserve University, Cleveland, Ohio. The same results were obtained with β AP₁₂₈.

Ten microgram β AP₁₂₈ and 10 μ l CSF were incubated in a 40 μ l PBS, pH 7.2 overnight at 37°C. The sample was analyzed by SDS-PAGE and immunoblotting. (Fig. 3(b)). The membrane was cut lengthwise in two strips. One strip was immunostained with rabbit anti- β AP antibody SGY2134 (lane 1); the other strip was immunostained with sheep anti-TTR antibody, ICN Biochemicals, Inc. (lane 2). Immunoreactive proteins were detected by ECL method (Amersham). The same results were obtained with β AP₁₄₀.

35

- 27 -

o

Only TTR- β AP complexes with an apparent molecular weight of 30 kDa under non-reducing conditions were observed (Fig. 3). Complexes of β AP with purified albumin or with albumin in CSF were not detected. Thus, radioiodination of β AP by Bolton-Hunter reagent may cause the nonspecific binding of radiolabeled peptide to albumin.

Example 3

10

The effect of β AP binding proteins on aggregation of unlabeled β AP₁₋₂₈ was tested by a quantitative thioflavin-T fluorometric assay (H. Levine III. *Protein Science* 2, 404 (1993). TTR was purchased from Calbiochem; bovine serum albumin, fraction V, was from Sigma; human serum apoE3 and apoE4 were isolated from human plasma as described by S.C. Rall, Jr., K.H. Weisgraber, R.W. Mahley, *Methods Enzymol.*, 128, 273 (1986)). It has been suggested that apoE may promote amyloid formation (T. Wisniewski, A. Golabek, E. Matsubara, J. Ghiso, and B. Frangione, *Biochem. Biophys. Res. Commun.* 192, 359 (1993). Therefore, in addition to TTR, two isoforms of apoE and albumin were tested. (Fig. 4). The effect of different concentrations of bovine serum albumin (crosses), TTR (squares), ApoE3 (triangles), and apoE4 (circles) on β AP₁₋₂₈ aggregation was determined using an thioflavin T based fluorometric assay.

25

One hundred percent aggregation equals the average fluorescence signal of β AP. Synthetic β AP₁₋₂₈ at 300 μ M in water was mixed with the indicated concentrations of BSA, TTR, apoE3, or ApoE4 and aggregation was initiated with 100 mM sodium acetate, pH 5.2. After 18 hours, 5 μ l samples were mixed with 10 μ M Thioflavin-T in 50 mM KPO₄ and the fluorescence was measured in arbitrary units at 450 nm excitation and 482 nm emission on a Perkin-Elmer LS-50 Fluorimeter (H. Levine III. *Protein Science* 2, 404 (1993). TTR was purchased from Calbiochem; bovine serum

30

35

- 28 -

albumin, fraction V, was from Sigma; human serum apoE3 and apoE4 were isolated from human plasma as described by S.C. Rall, Jr., K.H. Weisgraber, R.W. Mahley, *Methods Enzymol.*, **128**, 273 (1986)).

Transthyretin, apoE3 and apoE4 reduced the fluorescence signal, indicating the prevention of synthetic β AP₁₋₂₈ aggregation, while albumin had no effect (Fig. 4). Inhibition of β AP₁₋₂₈ aggregation was dose dependent with a 50% reduction in signal observed at 1.4 μ M for TTR and 0.4 μ M for apoE3 or apoE4.

When amyloid found in patient tissues or aggregated synthetic β AP is stained with congo red, it produces a specific green to yellow birefringence when viewed under polarized light (D.J. Selkoe, *Neuron* **6**, 487 (1991); D.L. Price, D.R. Borchelt and S.S. Sisodia, *Proc. Natl. Acad. Sci. U.S.A.* **90**, 6381 (1993). Congo red staining of β AP₁₋₂₈ aggregates in the presence of 5 μ M BSA (right panel) or 3 μ M TTR (left panel) was therefore determined. Figure 5. Synthetic β AP₁₋₂₈ at 300 μ M was mixed with 5 μ M BSA (left panel) or 3 μ M TTR (Fig. 5, right panel) and aggregation was initiated with 100 mM sodium acetate, pH 5.2. After 18 hours, samples were mixed with 0.2% Congo red in 100 mM sodium acetate, pH 5.2 and 5 μ l was spotted onto a microscope slide.

We found that the addition of albumin prior to aggregation of β AP₁₋₂₈ did not prevent the appearance of birefringence (Fig. 5, right panel). In contrast, when TTR or apoE was added to β AP₁₋₂₈ prior to aggregation, fewer or no characteristic aggregates producing birefringence were observed (Fig. 5, left panel).

Another feature of amyloid is the formation of fibrils with a characteristic electron microscopic pattern (D.J. Selkoe, *Neuron* **6**, 487 (1991); D.L. Price, D.R. Borchelt and S.S. Sisodia, *Proc. Natl. Acad. Sci. U.S.A.* **90**, 6381 (1993); E.M. Castano et al., *Biochem. Biophys. Res. Commun.* **141**, 782 (1986); D. Burdick et al., *J. Biol.*

- 29 -

Chem. 267, 546 (1992); J.T. Jarrett and P.T. Lansbury, Jr., Cell, 73, 1055 (1993)). Synthetic β AP₁₋₂₈ readily forms these typical 5-10 nm thick amyloid fibrils (Fig. 6, right panel). β AP₁₋₂₈ aggregates without (right panel) or with 2 μ M TTR (left panel) were analyzed using electron microscopy. One hundred microgram of β AP₁₋₂₈ was dissolved in water at concentration 100 μ g/ml, sonicated for 15 seconds, added to 2 μ M TTR, incubated for 16 hours at 37°C in PBS pH 7.2, and stained with 2% uranyl acetate. Samples were examined and photographed at magnification of 25,000 on a Hitachi-12 electron microscope.

When β AP was incubated with TTR, only amorphous masses with few abortive short fibrils were observed, suggesting that TTR prevented formation of characteristic fibrils (Fig. 6, left panel). ApoE3 or apoE4 had the same effect as TTR (data not shown).

Example 4

In order to define the binding sites of β AP and TTR we built three dimensional molecular models of the TTR- β AP complex on computers. The molecular and solvent accessible surfaces of β AP and TTR were generated and electrostatic potentials were calculated using the Poisson-Boltzmann equation. We conducted these modellings on a Silicon Graphics Iris, 220 GTX. Coordinates for β AP₁₋₂₈ correspond to the solution structure as determined by 2D-NMR and distance geometry/simulated annealing (J. Talafous, K.J. Marciniowski, G. Klopman and M.G. Zagorski, manuscript submitted for publication). Coordinates for the structure of TTR had been determined by X-ray crystallography (C.C.F. Blake, M.J. Geisow, and S.J. Oatley, J. Mol. Biol. 121, 339 (1978)). It is strikingly clear that the electrostatic potentials of the alpha helical β AP₁₋₂₈ are very dipolar in nature (Fig. 7, top panel). Likewise, TTR has clearly demarcated regions that

- 30 -

spawn negative (-) or positive (+) electrostatic potentials (Fig. 7, center panel). The binding sites on BAP and TTR which would give the best fit between BAP and TTR were determined using the following constraints: (1) maximize surface contacts; (2) maintain the relative orientations to enhance electrostatic attraction; (3) bind the amyloid peptide to each subunit of TTR independently; and (4) avoid the TTR monomer surface involved in tetramer formation. Using these constraints we identified the binding scheme which is shown in Figure 7, bottom panel, with TTR subunits (gray) and two BAP₁₋₂₈ molecules (white).

Top (BAP) and center (TTR dimer) panels represent molecular surfaces shown in white and calculated electrostatic potentials shown as surface contours. The -1 kT potential contour is shown by the grid labelled (-) and the +1 kT potential contour is shown by the grid labelled (+). Bottom panel represent TTR-BAP₁₋₂₈ complex as a space filling model. For clarity monomers of TTR dimer are shown in shades of gray. Two BAP molecules are shown in white (19).

The following amino-acid residues were found on the contacting surface of BAP: Arg (5), Ser (8), Gly (9), Val (12), His (13), Gln (15), Lys (16), Phe (19), Phe (20), Asp (23), Val (24), Asn (27), Lys (28).

In addition, the following amino-acid residues were found on the contacting surface of TTR dimer: Arg (34, 161), Ala (37, 164), Asp (38, 165), Thr (40, 167), Glu (42, 169), Glu (62, 189), Val (65, 192), Glu (66, 193). The first number in parenthesis is the residue number for the first subunit and the second number for the second subunit of TTR.

While not wishing to be bound by theory, we believe that the specific contribution of the amino acids on the TTR surface which binds specifically to the BAP peptide is twofold. First, they provide the building blocks for the detailed shape of the surface. Second, they provide the

- 31 -

charge that engenders a positive electrostatic potential which covers the whole surface with a value of +1 kT (at T =298 °K, k is the Boltzmann constant) at approximately 2 to 5 Å from the solvent accessible surface. A concave, positive potential inducing surface of β AP₁₋₂₈ containing the residues Arg (5), His (13), Lys (16) and Lys (28) was identified which matches remarkably well with the convex negative potential inducing surface on TTR containing the residues Asp (38, 165), Glu (42, 169), Glu (62, 189), and Glu (66, 193).

Our experiments clearly show that sequestered β AP cannot participate in amyloid fibril formation. While TTR is not the only protein that binds β AP (W.J. Strittmatter et al., *Proc. Natl. Acad. Sci. U.S.A.* **90**, 8098 (1993); J. Ghiso et al., *Biochem. J.* **293**, 27 (1993); W.J. Strittmatter et al., *Experimental Neurology* **122**, 327 (1993)), it is the major β AP sequestering protein in human CSF. The concentration of TTR is two orders of magnitude greater than concentration of β AP and is higher than the concentration of other known β AP binding proteins in CSF. The approximate concentrations are 3 nM for β AP, 2 μ M for albumin, 0.3 μ M for TTR, 0.1 μ M for apoE, 0.03 μ M for apoJ, and 0.03 μ M for APP (P. Seubert et al., *Nature* **359**, 325 (1992); M. Shoji et al., *Science* **258**, 126 (1992); B.A. Yankner, L.K. Duffy and D.A. Kirschner, *Science* **250**, 279 (1990); D.M. Araujo and C.W. Cotman, *Brain Res.* **569**, 141 (1992); M.P. Matson, et al., *J. Neurosci.* **12**, 376 (1992); C. Behl, J. Davis, G.M. Cole and D. Schubert, *Biochem. Biophys. Res. Commun.* **186**, 944 (1992)). Our data do not exclude the possibility that other proteins form complexes with β AP; however, most, if not all, β AP is probably sequestered by TTR (Figs. 1 and 3).

- 32 -

Example 5

Identification of TTR mutation.

Genetic linkage studies have reported several loci for familial AD (FAD) on chromosomes 21,14,19. However many FAD pedigrees have not shown evidence for linkage to these chromosomes, suggesting a genetically heterogeneous mechanism of disorder and existence of additional FAD susceptible genes.

Because of TTR's importance in amyloid formation, the TTR gene could be a candidate for FAD and sporadic AD in families not linked to defined genetic loci on chromosomes 14,19 and 21 or modulate effect of defined loci.

In order to identify a mutation in the TTR gene associated with AD, we have analyzed by PCR-Single Strand Conformation Polymorphism (SSCP), the sequence of three TTR exons in 55 unrelated AD patients.

PCR-SSCP analysis was performed according to the method of Orita et al. (Orita M, Suzuki Y, Sekiya T., Hayashi K., Genomics 5: 874-879). In all cases, one 5' end-labeled primer and one unlabeled primer were used for genomic PCR amplification. Oligonucleotides for all exons are listed in Table 1.

TABLE 1

Exon	Oligonucleotide	Position
2	5'CGC TCC AGA TTT CTA ATA CCAC 3'	1515-1537
	5'AGT GAG GGG CAA ACG GGA AGAT 3'	1791-1769
3	5'TGG TGG GGG TGT ATT ACT TTGC 3'	3446-3468
	5'CAT TTC CTG GAA TGC CAA AAGC 3'	4022-4000
4	5'GGT CAG TCA TGT TGT TCA TCTG 3'	7193-7215
	5'TAG TAA AAA TGG AAT ACT CTTG 3'	7447-7425

- 33 -

Primers were 5' end labeled with 32p-ATP using T4 polynucleotide kinase according to manufacturers instructions (New England BioLabs). The PCR mixture contained 12.5 ng of both primers, 5nmol of dNTP, 250 ng of genomic DNA and 1.25 U of AmpliTag polymerase (Perkin-Elmer Cetus). PCR was performed in a Perkin ElmerCetus DNA thermal cycler for 30 cycles (each cycle was 94 C-1min, 56 C-1 min, 72 C -2min, Extension 72-10 min. Electrophoresis was carried out at 4 C in 6% polyacrylamide gel.

PCR-SCCP revealed a polymorphism in exon 2 in 7 patients with AD. The amplified sequence of exon 2 was cloned in the pCR™ vector (Invitrogen) and target DNA was sequenced using a DNA Sequencing KIT (USB).

Ten (10) patients had a heterozygous G-A substitution in codon 6, which changed the normal glycine codon, GGT, to one for serin, AGT. This TTR variant originally was described as a variant with elevated thyroxine-binding affinity (Fitch N.J.S. et al., Journal of Endocrinology, 1991, 129, 309-313.). Although the gene frequency of the serine 6 TTR variant was found to be 12% in North American Caucasians (Jacobsen et al. supra.), we have found that the frequency of this variant in our random selected population of AD patients increased up to 18%.

G-A substitution in serine 6 variant of TTR creates a BsrI site. This enzyme might therefore be used for RFLP analysis of the TTR gene in AD pedigrees. Using the same conditions and the same primers for exon 2 (Table 1), we analyzed the PCR product for the presence of the BsrI restriction site (Fig. 8). These data show that the serine 6 TTR variant, as well as other TTR variants, could be associated with AD and can provide a genetic diagnostic test for some forms of AD.

While we have hereinbefore described a number of embodiments of this invention, it is apparent that the basic constructions can be altered to provide other

- 34 -

°
embodiments which utilize the methods of this invention.
Therefore, it will be appreciated that the scope of this
invention is defined by the claims appended hereto rather
than by the specific embodiments which have been presented
hereinbefore by way of example.

WE CLAIM:

1. A method of preventing aggregation of free β AP comprising, providing a β AP-binding compound (BBC) to β AP present in a solution wherein the BBC is provided in an amount sufficient to form a BBC- β AP complex and wherein
5 the BBC is capable of preventing amyloid formation by the β AP.

2. The method of preventing aggregation of β AP according to claim 1, wherein the BBC comprises
10 a binding domain which binds to the surface of the β AP at a site defined by the amino acid residues Arg (5), Ser (8), Gly (9), Val (12), His (13), Gln (15), Lys (16), Phe (19), Phe (20), Asp (23), Val (24), Asn (27), and Lys (28), and wherein the BBC is provided to the
15 solution in an amount sufficient to decrease the concentration of free amyloid β -protein in the solution.

3. The method according to claim 2 wherein the BBC comprises a binding site which binds to amino acid
20 residues Arg (5), His (13), Lys (16), and Lys (28) of β AP.

4. The method according to claim 3 wherein the BBC is selected from the group consisting of TTR and apoE.

25 5. The method according to claim 5 wherein the complexes are stable in SDS.

6. The method according to claim 5 wherein the BBC is TTR.
30

7. The method according to claim 1 wherein the BBC is provided to the solution so as to achieve a ratio of BBC to soluble β AP of between about 1:100 to about 100:1.
35

- 40 -

o

8. The method according to claim 7 wherein the ratio is between about 1 to about 4.

9. The method according to claim 8 wherein the ratio is about 1 to about 2.

5

10. The method according to claim 8 wherein the BBC is TTR.

10

11. A method of determining the amount of soluble amyloid β -protein (β AP) present in a sample comprising the steps of

15

combining a sample comprising β AP with a BBC according to claim 1 and a known amount of soluble β AP, wherein the BBC is either soluble or bound to a solid support, and detecting the amount of β AP in the sample.

20

12. The method according to claim 11 wherein the BBC is TTR bound to a solid support and the known amount of soluble β AP is labelled to allow detection.

25

13. A composition for preventing the aggregation of β AP in a sample comprising the BBC according to claim 1 and a physiologically inert carrier.

14. The composition according to claim 13 wherein the BBC is TTR.

30

15. A method of reducing the amount of soluble β AP at a given concentration *in vivo* comprising, providing a BBC according to claim 1 to a mammal in an amount sufficient to bind to the soluble β AP so as to reduce the concentration of free β AP.

35

16. The method according to claim 15 wherein the BBC is TTR.

- 41 -

17. The method according to claim 16 wherein TTR is provided to the mammal by inducing endogenous production of TTR.

18. A method for detecting a person at risk for developing β AP associated amyloidosis comprising, obtaining a sample of DNA from a person and analyzing the DNA for the presence of a mutation in the TTR gene characterized by a substitution of serine for glycine at amino acid residue number 6.

19. The method according to claims 18 wherein the person is at risk for Alzheimer's Disease.

20. A compound capable of binding to β AP to prevent β AP aggregation wherein the compound comprises a binding domain which binds to the surface of the β AP at a site defined by the amino acid residues Arg (5), Ser (8), Gly (9), Val (12), His (13), Gln (15), Lys (16), Phe (19), Phe (20), Asp (23), Val (24), Asn (27), and Lys (28), with the proviso that the BBC is not TTR.

21. The compound according to Claim 20 wherein the compound comprises a binding site which binds to amino acid residues Arg (5), His (13), Lys (16), and Lys (28) of amyloid β -protein.

22. The compound according to claim 21 wherein the compound is a polypeptide.

INTERNATIONAL SEARCH REPORT

I. national application No.
PCT/US94/12584

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1. In order for all inventions to be examined, the appropriate additional examination fees must be paid.

Group I, claims 1-14 and 20-22, drawn to an in vitro method to prevent aggregation of β AP in a sample, a composition and a compound, classified respectively in Class 435, subclass 7.1 and Class 530, subclass 350+.

Group II, claims 15-17, drawn to an in vivo method to prevent aggregation of β AP, classified in Class 514, subclass 2.

Group III, claims 18 and 19, drawn to a method of assaying DNA to determine if a person is at risk for Alzheimer's Disease, classified in Class 435, subclass 6.

The inventions listed as Groups I-III do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: The invention of group I is drawn to an in vitro method of assay to determine the amount β AP present in a sample and a method to prevent aggregation of β AP in the sample, along with compositions for said preventative step. The invention of group II is to a method of treating an individual. The invention of group III is to a method of assay by DNA analysis. Thus the in vitro methods require separate protocols for administration than the in vivo method. The in vitro methods are materially different as in group I, a protein is being measured and group II, DNA sequence is being analyzed. The methods are not required for each other. Accordingly, the claims are not so linked by a special technical feature within the meaning of PCT Rule 13.2 so as to form a single inventive concept.

SYNTHETIC INVERSO OR RETRO-INVERSO T-CELL EPITOPES

TECHNICAL FIELD

The present invention relates to synthetic T cell epitope analogues of native T cell epitopes with partial or complete inverso or retro-inverso modifications. These T cell epitope analogues stimulate immune responsiveness when used in place of their native T cell epitope counterparts in vaccines. The invention further relates to the use of these T cell epitope analogues, to vaccines comprising the T cell epitope analogues, to methods of preparing vaccines comprising these T cell epitope analogues, and to antibodies generated using these T cell epitope analogues.

BACKGROUND ART

The stereochemistry of polypeptides can be described in terms of the topochemical arrangement of the side chains of the amino acid residues about the polypeptide backbone which is defined by the peptide bonds between the amino acid residues and the α -carbon atoms of the bonded residues. In addition, polypeptide backbones have distinct termini and thus direction.

The majority of naturally occurring amino acids are L-amino acids. Naturally occurring polypeptides are largely comprised of L-amino acids.

D-amino acids are the enantiomers of L-amino acids and form peptides which are herein referred to as inverso peptides, that is, peptides corresponding to native peptides but made up of D-amino acids rather than L-amino acids.

Retro-inverso modification of naturally occurring polypeptides involves the synthetic assemblage of amino acids with α -carbon stereochemistry opposite to that of the corresponding L-amino acids, i.e. D- or D-allo-amino acids, in reverse order with respect to the native peptide sequence. A retro-inverso analogue thus has reversed termini and reversed direction of peptide bonds

while approximately maintaining the topology of the side chains as in the native peptide sequence.

Partial retro-inverso peptide analogues are polypeptides in which only part of the sequence is reversed and replaced with enantiomeric amino acid residues. Since the retro-inverted portion of such an analogue has reversed amino and carboxyl termini, the amino acid residues flanking the retro-inverted portion are replaced by side-chain-analogous α -substituted geminal-diaminomethanes and malonates, respectively.

Processes for synthesis of retro-inverso peptide analogues (Bonelli et al., 1984; Verdini and Viscomi, 1985) and some processes for the solid-phase synthesis of partial retro-inverso peptide analogues have been described (Pessi et al., 1987).

It has been observed that due to the stereospecificity of enzymes with respect to their substrates, replacement of L-amino acid residues with D-amino acid residues in peptide substrates generally abolishes proteolytic enzyme recognition and/or activity, although exceptions are known.

Peptide hormones have been of particular interest as targets for retro-inversion, presumably because their analogues would have potential use as therapeutic agents. Partial, and in a few cases complete, retro-inverso analogues of a number of peptide hormones have been prepared and tested (see, for example, Goodman and Chorev, 1981).

Complete or extended partial retro-inverso analogues have generally been found to be devoid of biological activity. The lack of biological activity has been attributed to possible complex structural changes caused by extended modification, the presence of reversed chain termini or the presence of proline residues in the sequences. Some partial retro-inverso analogues, that is peptides in which only selected residues were modified, on the other hand, have been shown to retain or enhance biological activity. Retro-inversion has also found

application in the area of rational design of enzyme inhibitors.

5 The fact that retro-inversion of biologically active peptides has met with only limited success in retaining or enhancing the activity of the native peptide is probably due to several reasons. Although structurally very similar, it was realised early that peptides and their retro-enantiomers are topologically not identical and crystal structure and solution conformation studies 10 have borne this out. Biological activity of a peptide hormone or neurotransmitter depends primarily on its dynamic interaction with a receptor, as well as on transduction processes of the peptide-receptor complex. It is now clear that such interactions are complex 15 processes involving multiple conformational and topological properties. Consequently it is not surprising that a retro-inverso analogue may not be able to mimic all of these properties.

20 In order to activate the cellular component of the immune system a vaccine must present T-cell epitopes, as well as pathogen-specific B-cell epitopes. T cells fail to recognise soluble antigen. They require its presentation on the surface of antigen presenting cells (APC) in association with molecules encoded by the major 25 histocompatibility complex (MHC). In the case of large proteins which constitute conventional vaccines, the protein undergoes enzymatic digestion intracellularly. Some of the resulting peptide fragments can bind to MHC molecules and the peptide-MHC complexes are then 30 transported to the surface of APCs. The peptides capable of binding MHC molecules are T-cell epitopes. Because of the genetic restriction of the MHC, the sequences which can act as T-cell epitopes may vary amongst individuals in an outbred population. Totally synthetic vaccines 35 (Jolivet et al., 1990) therefore need to be designed with regard to these facts. While it is possible to provide T-cell epitopes in a peptide vaccine by conjugation of the relevant B-cell epitope peptides to a carrier protein

such as tetanus toxoid, this is not desirable because it negates the inherent advantages of a peptide vaccine, e.g. chemical stability and ease of production. The identification of appropriate T-cell epitope 'cocktails' potentially useful in synthetic vaccines is therefore an active field of research (Schwartz, 1986).

DISCLOSURE OF THE INVENTION

Definitions

Throughout the specification and claims "retro modified" refers to a peptide which is made up of L-amino acids in which the amino acid residues are assembled in opposite direction to the native peptide with respect to which it is retro modified.

Throughout the specification and claims "inverso modified" refers to a peptide which is made up of D-amino acids in which the amino acid residues are assembled in the same direction as the native peptide with respect to which it is inverso modified.

Throughout the specification and claims "retro-inverso modified" refers to a peptide which is made up of D-amino acids in which the amino acid residues are assembled in the opposite direction to the native peptide with respect to which it is retro-inverso modified.

Throughout the specification and claims the term "native" refers to any sequence of L amino acids used as a starting sequence for the preparation of partial or complete retro, inverso or retro-inverso analogues.

The term "peptide" as used throughout the specification and claims is to be understood to include peptides of any length.

Throughout the specification and claims the term "antigenic fragment" refers to a peptide which is a portion of an antigen which itself is immunogenic or capable of binding antibodies.

The term "antigen" as used throughout the specification and claims is to be understood to include immunogens as the context requires.

Throughout the specification and claims the term "antigen analogue" refers to a peptide molecule capable of mimicking the immunological activity of the native peptide antigen with respect to which it is partially or completely retro, inverso or retro-inverso modified. Retro peptides are made up of L-amino acids and are peptides in which the amino acid residues are assembled in opposite direction to the native peptide sequence.

Throughout the specification and claims the term "T-cell epitope analogue" refers to a peptide molecule capable of mimicking the immunological activity of the native T-cell epitope with respect to which it is partially or completely inverso or retro-inverso modified.

Partial modification includes analogues in which as few as two consecutive residues are modified. Typically at least 5 or 6 consecutive residues are modified.

The present invention relates to partially or completely inverso or retro-inverso modified T-cell epitope analogues of native T cell epitopes which stimulate immune responsiveness when used in place of their native T cell epitope counterparts in vaccines. Incorporation of D-amino acids into T-cell epitope analogues increases their stability to degradation after administration. Further, incorporation of D-amino acids has potential for oral administration of analogues.

Having shown that particular retro-inverso or inverso T-cell epitope analogues can stimulate immune responsiveness when used in the place of their native T-cell epitope counterparts it follows that, generally, these analogues can be expected to be successful since T-cell epitope - MHC molecule interactions are not fundamentally different from case to case.

In a first aspect the invention provides a synthetic peptide T cell epitope analogue of a native T cell epitope, which analogue is partially or completely inverso or retro-inverso modified with respect to the native T cell epitope.

The T cell epitope analogues of the present invention stimulate immune responsiveness when used in place of their native T cell epitope counterparts in vaccines.

5 The efficacy of T cell epitope analogues of the invention is illustrated with respect to the malaria T cell epitopes of Example 2.

10 In a second aspect the invention provides a vaccine comprising a T cell epitope analogue of the first aspect together with a B cell epitope and a pharmaceutically or veterinarily acceptable carrier, diluent, excipient and/or adjuvant. Typically, the vaccines of the invention are cocktails of T cell epitope analogues and B cell epitopes tailored to the condition against which
15 vaccination is required. Preferably the T cell epitope analogue is conjugated to the B cell epitope.

The B cell epitope is conjugated to the T cell epitope by standard chemical conjugation techniques or the conjugate is synthesized as a continuous peptide.

20 The B cell epitope can be provided as any epitope, or any intact molecule providing the epitope, against which an antibody response is required.

The B cell epitopes to be incorporated into vaccines in accordance with the invention include peptides or
25 polypeptides of any length whose amino acid sequences stem from polypeptides of pathogens such as poliomyelitis, hepatitis B, foot and mouth disease of livestock, tetanus, pertussis, HIV, cholera, malaria, influenza, rabies or diphtheria causing agents, or toxins
30 such as robustoxin, heat labile toxin of pathogenic *Escherichia coli* strains and Shiga toxin from *Shigella dysenteriae*. Other B cell epitopes of interest include epitopes of Amyloid β protein (Alzheimer's disease) and human chorionic gonadotropin and gonadotropin releasing
35 hormone (contraceptive vaccines).

The B cell epitope is preferably a retro, retro-inverso or inverso antigen analogue.

Preferred T cell epitope analogues of the invention

are analogues of:

Diphtheria toxin:

H-Gln-Val-Val-His-Asn-Ser-Tyr-Asn-Arg-Pro-Ala-Tyr-Ser-Pro-Gly-OH (SEQ ID NO: 1)

5 Pertussis toxin:

H-His-Arg-Met-Gln-Glu-Ala-Val-Glu-Ala-Glu-Arg-Ala-Gly-Arg-OH (SEQ ID NO: 2)

Malaria CSA protein:

10 H-Pro-Ser-Asp-Lys-His-Ile-Glu-Gln-Tyr-Leu-Lys-Lys-Ile-Lys-Asn-Ser-Ile-Ser-OH (SEQ ID NO: 3)

Malaria CSB protein:

H-His-Ile-Glu-Gln-Tyr-Leu-Lys-Lys-Ile-Lys-Asn-Ser-Ile-Ser-OH (SEQ ID NO: 4)

Malaria CST3 protein:

15 H-Gly-Asp-Ile-Glu-Lys-Lys-Ile-Ala-Lys-Met-Glu-Lys-Ala-Ser-Ser-Val-Phe-Asn-Val-Val-Asn-Ser-OH (SEQ ID NO: 5)

Hen egg lysozyme:

H-Cys-Ser-Ala-Leu-Leu-Ser-Ser-Asp-Ile-Thr-Ala-Ser-Val-Asn-Cys-Ala-OH (SEQ ID NO: 6)

20 Ovalbumin:

H-Ile-Ser-Gln-Ala-Val-His-Ala-Ala-His-Ala-Glu-Ile-Asn-Glu-OH (SEQ ID NO: 7) and

H-Tyr-Thr-Tyr-Thr-Val-His-Ala-Ala-His-Ala-Tyr-Thr-Tyr-Thr-OH (SEQ ID NO: 8)

25 Other preferred T cell epitope analogues are analogues of:

Measles Virus F and H glycoproteins: (Partidos C.D. et al, 1991)

30 MVF:258-277 H-Gly-Ile-Leu-Glu-Ser-Arg-Gly-Ile-Lys-Ala-Arg-Ile-Thr-His-Val-Asp-Thr-Glu-Ser-Tyr-OH (SEQ ID NO: 9)

MVF:288-302 H-Leu-Ser-Glu-Ile-Lys-Gly-Val-Ile-Val-His-Arg-Leu-Glu-Gly-Val-OH (SEQ ID NO: 10)

35 Respiratory syncytial virus 1A protein: (Nicholas J.A. et al, 1988)

20 In a third aspect the invention provides a method of vaccinating a host in need of such treatment which method comprises administering an effective amount of a vaccine according to the second aspect to the host.

25 In a fourth aspect the invention provides antibodies produced by immunisation of a host with a vaccine of the second aspect.

In a fifth aspect the invention provides a method of preparing a T cell epitope analogue of the invention comprising synthesising a partially or completely inverso or retro-inverso peptide comprising the analogue.

30 In a sixth aspect the invention provides a method of preparing a vaccine of the second aspect comprising conjugating a T cell epitope analogue of the first aspect to a B cell epitope or admixing a T cell epitope analogue of the first aspect with a B cell epitope and admixing an effective amount of the resulting mixture or conjugate
 35 with a pharmaceutically or veterinarily acceptable carrier, diluent, excipient and/or adjuvant.

Vaccines of the invention can be formulated using

standard methods in the art of vaccine formulation.

Selection of appropriate diluents, carriers, excipients and/or adjuvants can be made in accordance with standard techniques in the art.

5 Vaccines of the invention may be administered to hosts in need of such treatment by injection. Vaccines incorporating D-amino acid containing analogues may also be administered orally.

ABBREVIATIONS

10	BOP	(benzotriazolyloxy)tris(dimethylamino) phosphonium hexafluorophosphate (Castro's reagent)
	DMF	dimethyl formamide
	ELISA	enzyme-linked immunosorbent assay
15	Fmoc	9-fluorenylmethoxycarbonyl
	HPLC	high-performance liquid chromatography
	Ig	immunoglobulin

	TFA	trifluoroacetic acid

Amino Acids:

L-amino acids are indicated by an upper case followed by lower case lettering e.g. Ala indicates
30 L-alanine.

D-amino acids are indicated by all lower case abbreviations, e.g. ala indicates D-alanine.

BRIEF DESCRIPTION OF THE FIGURES

Figure 1 shows the results of a cell proliferation
35 experiment conducted using the T-cell epitope peptides

noMalCST3 (SEQ ID NO: 5), inMalCST3 and riMalCST3.

Figure 2 shows antibody production measured in mice immunized with the B-cell epitope H-(Asn-Ala-Asn-Pro)₃-OH (SEQ ID NO: 23) alone or together with either no or
5 riMalCST3.

Figure 3 shows antibody production measured in mice immunized with the B-cell epitope H-(Asn-Ala-Asn-Pro)₃-OH (SEQ ID NO: 23) alone or together with either no (SEQ ID NO: 3) or riMalCSA protein.

10 Figure 4 shows antibody production measured in mice immunized with the B-cell epitope H-(Asn-Ala-Asn-Pro)₃-OH (SEQ ID NO: 23) alone or together with either no (SEQ ID NO: 4) or riMalCSB protein.

Figure 5 shows antibody production measured in mice
15 immunized with the B-cell epitope H-(Asn-Ala-Asn-Pro)₃-OH (SEQ ID NO: 23) alone or together with either no (SEQ ID NO: 1) or riDiphT.

Figure 6 shows antibody production measured in mice immunized with the B-cell epitope H-(Asn-Ala-Asn-Pro)₃-OH
20 (SEQ ID NO: 23) alone or together with either no (SEQ ID NO: 2) or riPertT.

Figure 7 shows antibody production measured in mice immunized with the B-cell epitope H-(Asn-Ala-Asn-Pro)₃-OH (SEQ ID NO: 23) alone or together with either no (SEQ ID
25 NO: 7) or riOvalT.

BEST MODE OF CARRYING OUT THE INVENTION

T cell epitope analogues of the invention are prepared by standard techniques for the preparation of L and D amino acid containing peptides, particularly as
30 outlined in Example 1.

Vaccines of the invention are formulated by standard techniques for vaccine formulation using standard carriers, diluents excipients and/or adjuvants suitable for the formulation of oral or injectable vaccines.
35 Effective amounts of Tcell-epitope analogues to be incorporated in the vaccines can be determined in accordance with standard methods. Conjugation techniques

where used are standard chemical conjugation techniques.

The vaccination regimes used are standard regimes for the vaccination of animal or human hosts. These regimes can be used where immunisation of the host is
5 desired or where the host is being used to produce antibodies for exogenous use.

The invention is further described in the following examples which are illustrative of the invention but in no way limiting on its scope.

10

EXAMPLE 1

Peptide Synthesis

Peptides were synthesised by a solid-phase method on polyamide (Arshady et al., 1981) or Polyhipe supports using side-chain protected Fmoc amino acids (Carpino &
15 Han, 1972), essentially as described by Eberle et al. (1986). Only pure amino acid derivatives, obtained commercially or by synthesis, were used. The polyamide synthesis resins, derivatised with p-alkoxybenzyl alcohol-based linkage agents, were esterified
20 quantitatively with the appropriate preformed C-terminal Fmoc-amino acid symmetrical anhydrides, in the presence of 0.2 molar equivalents of N,N-dimethylaminopyridine and N-methylmorpholine. The Polyhipe resin, derivatised with Fmoc-Rink linker (Rink, 1987) did not require
25 esterification of the first amino acid linked to it. Chain elongation was carried out using Fmoc-amino acid pentafluorophenyl esters (Atherton et al., 1988) or Castro's reagent/1-hydroxybenzotriazole coupling (Hudson, 1988). The progress of each synthesis was monitored
30 using a specific colour test (Hancock & Battersby, 1976) and/or amino acid analysis of acid-hydrolysed peptidyl resin samples.

The peptides were cleaved from the resins and side-chain deprotected with the aid of TFA, containing a
35 suitable mixture of scavenger chemicals (Tam, 1988). After filtration and vacuum evaporation, the peptides were triturated with diethyl ether, collected by

centrifugation and lyophilised from aqueous ammonium bicarbonate solution.

All peptides then underwent an initial desalting and purification step by column chromatography on suitable gel filtration media in aqueous solvents. Afterwards they were purified to homogeneity by reversed-phase HPLC using water-acetonitrile (containing 0.05-0.1% TFA) gradient elution. The purity of the synthetic peptides was further assessed by gas-phase acid hydrolysis/amino acid analysis (Biddingmeyer et al., 1987) and, if deemed necessary, by automated gas-phase sequencing (Hunkapiller & Hood, 1983).

EXAMPLE 2

Malaria T-cell epitope peptides

It has been shown that nonresponsiveness to the malaria immunodominant B-cell epitope (Asn-Ala-Asn-Pro)_x (SEQ ID NO: 23) of the *Plasmodium falciparum* circumsporozoite protein can be overcome in the presence of a particular T-cell epitope peptide from the same protein (Sinigaglia et al, 1988). The peptide in question, unlike most T-cell epitopes, is recognised in association with most human MHC class II molecules and has been suggested as a suitable component of a synthetic peptide vaccine against malaria. The region of the circumsporozoite protein from which the peptide stems is apparently conserved in different parasite isolates.

The following peptides were prepared according to the usual protocols:

noMalCST3	H-Gly-Asp-Ile-Glu-Lys-Lys-Ile-Ala-Lys-Met-Glu-Lys-Ala-Ser-Ser-Val-Phe-Asn-Val-Val-Asn-Ser-OH (SEQ ID NO: 5)
inMalCST3	H-Gly-asp-ile-glu-lys-lys-ile-ala-lys-met-glu-lys-ala-ser-ser-val-phe-asn-val-val-asn-ser-OH
35 riMalCST3	H-ser-asn-val-val-asn-phe-val-ser-ser-ala-lys-glu-met-lys-ala-aile-lys-lys-glu-aile-asp-Gly-OH

BALB/c mice were immunised subcutaneously at the base of the tail with the above T-cell epitope peptides emulsified in an equal volume of complete Freund's adjuvant. Ten days later, the animals were killed by cervical dislocation and the inguinal and popliteal lymph nodes removed. A cell suspension from the lymph nodes was prepared and the cells cultured in the presence of various concentrations of the test antigen, as well as a non-related control antigen. Cell proliferation was quantitated by measuring the incorporation into the cells of radiolabelled thymidine. Results from the experiment are shown in Fig. 1.

When animals were primed with any form of the peptide and the animals' cultured T cells challenged with the same peptide, proliferation was observed in every case. Upon priming with one form of a peptide and challenging with either of the other two forms, some activation was observed in each case.

In order to remove any potential effects due to non-specific cell proliferation, the T cell assay method was improved as follows:

A cell suspension from the lymph nodes was centrifuged on Ficoll-Isopaque to separate mononuclear cells from erythrocytes. The resulting cell preparation was washed extensively in PBS and incubated with Dynabeads coated with anti-mouse IgG to remove B-lymphocytes. The cells from this preparation were then cultured in the presence of various concentrations of the test antigen, as well as a non-related control antigen. Cell proliferation was quantitated by measuring the incorporation into the cells of radiolabelled thymidine and or by the use of Promega Cell Titer 96 AQ kit. Again efficacy of the T cell epitope analogues was demonstrated.

Antibody responses to synthetic peptides representing the immunodominant B-cell epitope H-(Asn-Ala-Asn-Pro)₃-OH (SEQ ID NO: 23) of the circumsporozoite protein were measured following intraperitoneal injection

of Balb/c mice. One hundred microgrammes of B-cell epitope were administered in an equal volume of Freund's complete adjuvant either alone or in a mixture (1:1) with either noMalCST3 (SEQ ID NO: 5) or riMalCST3. As a negative control, a further group of mice were immunised with either noMalCST3 (SEQ ID NO: 5) or riMalCST3 in the absence of the B-cell epitope. Three weeks after priming, mice were boosted by the same route and with the same dose of peptide in incomplete Freund's adjuvant. A second booster injection was given two weeks after the first with the same dose of antigen in incomplete Freund's adjuvant. Blood samples were taken five days later by retro-ocular bleeding and, after centrifugation, the sera was immediately used in an enzyme-linked immunosorbent assay (ELISA). Titres of antibodies against the B-cell epitope were determined in microtitre plates coated overnight at 4°C with 0.5 microgrammes of synthetic peptide cross-linked to ovalbumin.

Low titre of antibodies were measured in mice immunised with the B-cell epitope alone, however, much higher titre of antibodies was observed in each case in mice co-immunised with the same peptide and either form of the T-cell epitope (Fig.2). All together, these findings demonstrate the potential usefulness of riMalCST3 and inMalCST3 as vaccine components; the cellular immune response they elicit is responsive to the normal antigen.

Antibody response to the same B-cell epitope was also measured using five more T-cell epitopes selected from the literature and synthesized in the following forms:

Malaria circumsporozoite protein:

noMalCSA (Good et al, 1987):

H-Pro-Ser-Asp-Lys-His-Ile-Glu-Gln-Tyr-Leu-Lys-Lys-Ile-Lys-Asn-Ser-Ile-Ser-NH₂ (SEQ ID NO: 3)

riMalCSA:

H-ser-ile-ser-asn-lys-ile-lys-lys-leu-tyr-gln-glu-ile-his-lys-asp-ser-pro-NH₂

noMalCSB (Good et al, 1988):

H-His-Ile-Glu-Gln-Tyr-Leu-Lys-Lys-Ile-Lys-Asn-Ser-Ile-Ser-NH₂ (SEQ ID NO: 4)

riMalCSB:

5 H-ser-ile-ser-asn-lys-ile-lys-lys-leu-tyr-gln-glu-ile-his-NH₂

Diphtheria toxin:

noDipT (Bixler et al, 1989)

10 H-Gln-Val-Val-His-Asn-Ser-Tyr-Asn-Arg-Pro-Ala-Tyr-Ser-Pro-Gly-NH₂ (SEQ ID NO:1)

riDipT:

H-Gly-pro-ser-tyr-ala-pro-arg-asn-tyr-ser-asn-his-val-val-gln-NH₂

Pertussis toxin:

15 noPertT (Kim et al, 1990) (SEQ ID NO: 2):

H-His-Arg-Met-Gln-Glu-Ala-Val-Glu-Ala-Glu-Arg-Ala-Gly-Arg-NH₂

riPertT:

20 H-arg-Gly-ala-arg-glu-ala-glu-val-ala-glu-gln-met-arg-his-NH₂

Ovalbumin:

noOvalT (Sette et al, 1989) (SEQ ID NO: 7):

H-Ile-Ser-Gln-Ala-Val-His-Ala-Ala-His-Ala-Glu-Ile-Asn-Glu-NH₂

25 riOvalT:

H-glu-asn-ile-glu-ala-his-ala-ala-his-val-ala-gln-ser-ile-NH₂

30 The synthesis of the above peptides was performed on Polyhipe Rink resin. The side chain protecting groups used were: t-butyl for serine, threonine, aspartic acid, glutamic acid and tyrosine; trityl for histidine, glutamine and asparagine; t-butoxycarbonyl for lysine and 2,2,5,7,8-pentamethyl chroman-6-sulphonyl for arginine. For diphtheria and pertussis peptides, cleavage and side-
35 chain deprotection were accomplished by reaction of the peptidyl resins for 90 min at 0°C with 1M trimethylsilylbromide-thioanisole in TFA containing 0.25M 1,2-ethanedithiol (5% v/v) and water (5% v/v) in TFA at

room temperature for 90 min.

In each case the mice developed very low titres against the B-cell epitope when immunised with the B-cell epitope alone, but produced much higher antibody titre
5 when a mixture of the B-cell epitope and any of the T-cell epitopes in either no- or ri- form were used in the immunogen formulation (Fig. 3-7).

INDUSTRIAL APPLICATION

T cell epitope analogues in accordance with the
10 invention have a range of potential applications in eliciting immunogenic responses in a host. These analogues can be used in the treatment and/or prophylaxis of diseases, and therapy of disease states. In particular, these analogues can be used in vaccines in
15 animals, including humans for protection against pathogens and the like.

CLAIMS

1. A synthetic peptide T cell epitope analogue of a native T cell epitope which analogue is partially or completely inverso modified with respect to the native T cell epitope.

2. A synthetic peptide T cell epitope analogue of a native T cell epitope which analogue is partially or completely retro-inverso modified with respect to the native T cell epitope.

3. A synthetic peptide T cell epitope analogue according to claim 1 or claim 2 wherein the native T cell epitope is selected from the group consisting of:

H-Gln-Val-Val-His-Asn-Ser-Tyr-Asn-Arg-Pro-Ala-Tyr-Ser-Pro-Gly-OH, from diphtheria toxin (SEQ ID NO: 1);

H-His-Arg-Met-Gln-Glu-Ala-Val-Glu-Ala-Glu-Arg-Ala-Gly-Arg-OH, from pertussis toxin (SEQ ID NO: 2);

H-Pro-Ser-Asp-Lys-His-Ile-Glu-Gln-Tyr-Leu-Lys-Lys-Ile-Lys-Asn-Ser-Ile-Ser-OH, from malaria CSA protein (SEQ ID NO: 3);

H-His-Ile-Glu-Gln-Tyr-Leu-Lys-Lys-Ile-Lys-Asn-Ser-Ile-Ser-OH, from malaria CSB protein (SEQ ID NO: 4);

H-Gly-Asp-Ile-Glu-Lys-Lys-Ile-Ala-Lys-Met-Glu-Lys-Ala-Ser-Ser-Val-Phe-Asn-Val-Val-Asn-Ser-OH, from malaria CST3 protein (SEQ ID NO: 5);

H-Cys-Ser-Ala-Leu-Leu-Ser-Ser-Asp-Ile-Thr-Ala-Ser-Val-Asn-Cys-Ala-OH, from hen egg lysozyme (SEQ ID NO: 6);

H-Ile-Ser-Gln-Ala-Val-His-Ala-Ala-His-Ala-Glu-Ile-Asn-Glu-OH (SEQ ID NO: 7) and

H-Tyr-Thr-Tyr-Thr-Val-His-Ala-Ala-His-Ala-Tyr-Thr-Tyr-

Thr-OH (SEQ ID NO: 8), from ovalbumin;

MVF:258-277 H-Gly-Ile-Leu-Glu-Ser-Arg-Gly-Ile-Lys-Ala-Arg-Ile-Thr-His-Val-Asp-Thr-Glu-Ser-Tyr-OH (SEQ ID NO: 9)

and

MVF:288-302 H-Leu-Ser-Glu-Ile-Lys-Gly-Val-Ile-Val-His-Arg-Leu-Glu-Gly-Val-OH (SEQ ID NO: 10), from measles virus F and H glycoproteins;

RS1A:45-60 H-Cys-Glu-Tyr-Asn-Val-Phe-His-Asn-Lys-Thr-
Phe-Glu-Leu-Pro-Arg-Ala-OH (SEQ ID NO: 11),
from respiratory syncytial virus 1A protein;
Influenza hamagglutinin A/PR/8/34 Mt.S.: residues 109-119
5 (SEQ ID NO: 12), 130-140 (SEQ ID NO: 13), and 302-313
(SEQ ID NO: 14);
residues (A)4-14 (SEQ ID NO: 15) and (B)5-16 (SEQ ID NO:
16) from pork insulin;
Hepatitis B virus pre S residues 120-132 (SEQ ID NO: 17);
10 Hepatitis B virus major surface antigen: residues 38-52
(SEQ ID NO: 18), 95-109 (SEQ ID NO: 19), and 140-154 (SEQ
ID NO: 20);
Foot and mouth virus VP1: residues 141-160 (SEQ ID NO:
21); and
15 Rabies virus-spike glycoprotein precursor: residues 32-44
(SEQ ID NO: 22).

4. A T cell epitope analogue according to claim
2 or claim 3 wherein the amino acid residues flanking the
retro-inverted sequence are substituted by
20 side-chain-analogous α -substituted
geminal-diaminomethanes and malonates.

5. A vaccine comprising a T cell epitope
analogue according to any one of claims 1 to 4 together
with a B cell epitope and a pharmaceutically acceptable
25 carrier, diluent, excipient and/or adjuvant.

6. A vaccine according to claim 5 wherein the T
cell epitope analogue is conjugated to the B cell
epitope.

7. A vaccine according to claim 5 which is a
30 cocktail of T cell epitope analogues and B cell epitopes
tailored to the condition against which vaccination is
required.

8. A vaccine according to claim 5 wherein the B
cell epitope is a peptide or polypeptide of any length
35 whose amino acid sequences stem from:
polypeptides of a pathogen including poliomyelitis,
hepatitis B, foot and mouth disease of livestock,
tetanus, pertussis, HIV, cholera, malaria, influenza,

rabies or diphtheria causing agents;
a toxin including robustoxin, heat labile toxin of
pathogenic *Escherichia coli* strains and Shiga toxin from
Shigella dysenteriae;

- 5 Amyloid β protein;
human chorionic gonadotropin;
or gonadotropin releasing hormone.

9. A vaccine according to claim 5 wherein the B cell
epitope is a retro, retro-inverso or inverso antigen
10 analogue.

10. A method of vaccinating a host in need of such
treatment which method comprises administering an
effective amount of a vaccine according to claim 5 to the
host.

15 11. A method of preparing a T cell epitope
analogue according to claim 1 or 2, the method comprising
synthesising a partially or completely inverso or retro-
inverso analogue of the native T cell epitope.

20 12. Antibodies produced by immunisation of a host
with a vaccine according to claim 5.

13. A method of preparing a vaccine according to
claim 5 which method comprises: conjugating a T cell
epitope analogue according to claim 1 or claim 2 to a B
cell epitope, or admixing a T cell epitope analogue
25 according to claim 1 or claim 2 with a B cell epitope;
and admixing an effective amount of the resulting mixture
or conjugate with a pharmaceutically or veterinarily
acceptable carrier, diluent, excipient and/or adjuvant.

Antimicrobial Oil-In-Water Emulsions

Background of the Invention

5 The present invention relates to an antimicrobial lipid-containing oil-in-water emulsion which inactivates infectious pathogens upon contact.

 It is known that if a water-immiscible liquid phase is mixed into an aqueous phase by mechanical agitation, for example, by means of an ultra-disperser, the stability of the
10 resulting oil-in-water dispersion most frequently requires the addition of an emulsifying agent, the molecules of which are adsorbed onto the surface of the oil droplets to form a kind of continuous membrane which prevents direct contact between two adjacent droplets. The drops of oil can further contain substances soluble in an organic medium, such as a sterol.

15 In addition to discrete oil droplets dispersed in an aqueous phase, oil-in-water emulsions can also contain other lipid structures, such as small lipid vesicles (i.e., lipid spheres which often consist of several substantially concentric lipid bilayers separated from each other by layers of aqueous phase), micelles (e.g., amphiphile molecules in small clusters of 50-200 molecules arranged so that the polar head groups face outward toward the aqueous
20 phase and the apolar tails are sequestered inward away from the aqueous phase), or lamellar phases (lipid dispersions in which each particle consists of parallel glycerol ester bilayers separated by thin films of water). These lipid structures are formed as a result of hydrophobic forces which drive apolar residues (i.e., long hydrocarbon chains) away from water.

25 The portals of entry of pathogenic bacteria, viruses or fungi are predominantly the skin and mucus membranes, and upper and lower respiratory tracts. The first step in any infection is attachment or colonization on skin or mucus membranes with subsequent invasion and dissemination of the infectious pathogen. Accordingly, an object of the present invention is to provide an antimicrobial emulsion which inactivates infectious pathogens on
30 contact by disrupting their membrane structures.

Summary of the Invention

 The present invention provides a stable antimicrobial oil-in-water emulsion for inactivating infectious pathogens upon contact. The emulsion comprises positively charged
35 droplets of a lipid-containing oily "discontinuous phase" dispersed in an aqueous "continuous phase". It is believed that the oily discontinuous phase inactivates infectious pathogens by disrupting their membrane structure. The emulsion has microbicidal activity against a broad spectrum of bacteria, viruses and yeasts.

The antimicrobial emulsion of the present invention consists primarily of positively charged droplets of an oily discontinuous phase dispersed in an aqueous continuous phase, such as water. The discontinuous phase contains a glycerol ester selected from the group consisting of glycerol monooleate (GMO), glycerol trioleate (GTO), glycerol monolaurate (GMO), and glycerol dilaurate (GDL) and a cationic halogen-containing compound, preferably one having a C₁₂-C₁₆ chain as a positive charge producing agent. The droplets can further contain a sterol, such as cholesterol or phytosterol. The droplets appear to bind to negatively charged proteins contained in bacterial, viral, or fungal membranes, thereby disrupting the membrane structure and irradiating the pathogen.

Antimicrobial emulsions of the present invention are non-toxic and safe, for example, when swallowed, inhaled, or applied to the skin. This result is unexpected since many cationic halogen-containing compounds having a C₁₂-C₁₆ chain are extremely toxic if administered alone. For example, cetylpyridinium chloride (CPC), the preferred cationic halogen-containing compound of the invention, causes severe irritation and damage to tissues of the upper respiratory tract, mucous membranes and skin. However, when administered in the form of an emulsion of the invention, no such adverse effects occur. Furthermore, the emulsions of the invention are stable when heated or exposed to significant levels of acid and base.

The positive charge of the oily discontinuous phase is provided by a cationic halogen-containing compound having a C₁₂-C₁₆ chain. In a preferred embodiment, the cationic halogen-containing compound having a C₁₂-C₁₆ chain is selected from the group consisting of cetylpyridinium chloride (CPC), cetylpyridinium bromide (CPB), cetyltrimethylammonium bromide (CTAB), and cetyldimethylethylammonium bromide (CDEAB). Other cationic halogen-containing compounds having a C₁₂-C₁₆ chain which can be used include, for example, cetyltrimethylammonium chloride, cetylbenzyltrimethylammonium chloride, cetyltributylphosphonium bromide, dodecyltrimethylammonium bromide, and tetradecyltrimethylammonium bromide.

The oily discontinuous phase can further contain at least one sterol selected from the group consisting of cholesterol, cholesterol derivatives, hydrocortisone, phytosterol, and mixtures thereof. The term "cholesterol derivatives," as used herein, includes but is not limited to sulfate and phosphate derivatives of cholesterol. Preferred sterols include phytosterols, such as soya sterol.

Oils useful in forming antimicrobial oil-in-water emulsions of the present invention include a broad spectrum of water-immiscible materials, such as soybean oil, avocado oil, squalene oil, sesame oil, olive oil, canola oil, corn oil, rapeseed oil, safflower oil, sunflower

oil, fish oils, flavor oils, water insoluble vitamins, and mixtures thereof. In a preferred embodiment of the invention, the oil is a scented or flavored oil such as peppermint oil.

5 In another embodiment of the invention, at least a portion of the emulsion may be in the form of lipid structures including, but not limited to, unilamellar, multilamellar, and paucilamellar lipid vesicles, micelles, and lamellar phases.

10 The antimicrobial emulsions of the present invention can be used, for example, in pharmaceutical preparations (e.g., creams, solutions and suspensions) to inhibit the growth of a wide variety of infectious pathogens, including bacteria, viruses, and fungi. Accordingly, the present invention also provides an antimicrobial preparation suitable for pharmaceutical administration made up of an antimicrobial emulsion of the invention and a pharmaceutically acceptable carrier. The preparation can be applied topically to skin surface areas, mucus membranes, or oral surfaces, for example, as a cream, gel, spray, mouthwash, or deodorant to
15 treat or prevent bacterial infections such as *Propionibacterium acnes*, *Neisseria gonorrhea*, *Streptococcus*, and *Staphylococcus epidermidis*. Alternatively, the preparation can be administered internally by, for example, oral or intravenous administration. Such systemic administration of the preparation can be used, for example, to inactivate pathogenic microorganisms, e.g., bacteria such as *Helicobacter pylori*, and viruses, particularly envelope
20 viruses. In a preferred embodiment of the invention, the preparation is administered orally to an individual to treat infection by HIV.

Accordingly, the present invention further provides a method for inhibiting the growth of an infectious pathogen by topical or systemic administration of the antimicrobial
25 emulsion of the invention.

Detailed Description of the Invention

30 The present invention relates to a stable antimicrobial oil-in-water emulsion made of positively charged droplets of an oily discontinuous phase dispersed in an aqueous continuous phase.

35 The term "antimicrobial," as used herein, means having the ability to inactivate infectious pathogens. The term "inactivate", as used herein, includes but is not limited to, killing or inhibiting growth of the organism. The term "infectious pathogen", as used herein, includes, but is not limited to, fungi, viruses, bacteria, and parasites. The antimicrobial emulsion of the present invention inactivates a wide variety of infectious pathogens. It appears that inactivation is achieved by disruption of the membrane structure of the pathogen by the components of the oily discontinuous phase.

The term "emulsion," as used herein, includes both classic oil-in-water dispersions or droplets, as well as other lipid structures which can form as a result of hydrophobic forces which drive apolar residues (i.e., long hydrocarbon chains) away from water and drive polar head groups toward water, when a water immiscible oily phase is mixed with an aqueous phase. These other lipid structures include, but are not limited to, unilamellar, paucilamellar, and multilamellar lipid vesicles, micelles, and lamellar or hexagonal phases. These other lipid structures also contain a glycerol ester selected from the group consisting of glycerol monooleate (GMO), glycerol trioleate (GTO), glycerol monolaurate (GML), and glycerol dilaurate (GDL) as the primary emulsifier, and a dodacyl to hexadecyl cationic halogen-containing compound as a positive charge producing agent. These other lipid structures can also further include at least one sterol, preferably a phytosterol. In a preferred embodiment of the invention, GMO is used as the primary emulsifier. The term "primary emulsifier", as used herein, refers to the emulsifier which constitutes the greatest proportion by weight of any single emulsifier contained in the oily discontinuous phase.

Antimicrobial oil-in-water emulsions of the present invention can be formed using classic emulsion forming techniques which are well known in the art. In brief, the lipid-oil phase is mixed with the aqueous phase under relatively high shear forces to obtain an oil-in-water emulsion containing oil droplets which are approximately 1 micron in diameter. More particularly, a positively charged lipid-containing oily discontinuous phase is formed by blending (a) an oil carrier; (b) a glycerol ester selected from the group consisting of GMO, GTO, GML, or GDL; and (c) a cationic halogen-containing compound having a C₁₂-C₁₆ chain, along with any other compatible glycerol esters or emulsifiers, such as Polysorbate 60, and any sterols or other lipophilic materials to be incorporated into the lipid-oil phase.

Once the lipid-oil phase is formed, it is heated and blended with an aqueous phase (e.g., water, saline, or any other aqueous solution which can hydrate the lipids) on a volume to volume basis ranging from about 1:4 to 1:2, preferably about 1:3 lipid-oil phase to aqueous phase. The lipid-oil and aqueous phases can be blended using any apparatus capable of producing the high shear mixing forces, including, for example, a french press, a Novamix™ lipid vesicle maker (IGI Inc., Buena N.J.), a syringe mixer, or, alternatively by hand using two syringes as described in U.S. Patents Nos. 4,895,452 and 4,911,928, the teachings of which are incorporated by reference herein.

Antimicrobial oil-in-water emulsions of the present invention provide the advantage of being stable in the presence of heat, acid, or base. For example, as shown below in Example 7, emulsions of the invention are not significantly altered or broken down when

boiled or exposed to 1N nitric acid or 1N sodium hydroxide. This stability makes the emulsions suitable for pharmaceutical administration, even internal administration.

Antimicrobial oil-in-water emulsions of the present invention can be used to
5 inactivate a variety of infectious pathogens upon contact. As described in the examples below, microbes which are inactivated by the present invention include a wide variety of bacteria, fungi and viruses. More specifically, for inactivation of bacteria which colonize in oral or oropharyngeal areas, such as *Streptococcus pneumoniae*, Group A beta-hemolytic *Streptococcus*, *Haemophilus influenzae*, and *Neisseria meningitidis*, the presently disclosed
10 emulsions can be applied topically, as a spray or mouthwash. For bacteria which colonize in gastrointestinal areas, such as *Helicobacter pylori*, the emulsions can be administered orally, for example, as a pill or a liquid. For bacteria and fungi which colonize in the vagina, such as *Neisseria gonorrhoeae*, *Gardnerella vaginalis*, Group B *Streptococcus*, and *Candida albicans*, the emulsions can be applied topically as a cream, gel, or suppository. The
15 presently disclosed emulsions can also be used for dermatological application as a cream or gel to inactivate or prevent infection secondary to *Propionibacterium acnes*, *Staphylococcus aureus*, *Staphylococcus epidermidis*, and Group B *Streptococcus*. In a preferred embodiment of the invention, antimicrobial emulsions of the present invention are used to prevent infection by gram positive bacteria.

20

Antimicrobial oil-in-water emulsions of the present invention can also be used to inactivate a variety of viruses, particularly enveloped viruses upon contact. For example, the presently disclosed emulsions can be used for oropharyngeal, oral, venereal, dermatological, or internal application to inactivate or prevent infection secondary to viruses including
25 *Herpesviridae* (e.g., herpes simplex types 1 and 2, Epstein-Barr virus, cytomegalovirus, varicella virus, and human herpes virus type 6), *Togaviridae* (e.g., Rubella virus), *Flaviviridae*, (e.g., Yellow Fever virus), *Coronaviridae* (e.g., Corona viruses), *Rhabdoviridae* (e.g., Rabies virus), *Filoviridae* (e.g., Marburg virus), *Paramyxoviridae* (e.g., Measles virus), *Orthomyxoviridae* (e.g., Influenza viruses), *Bunyaviridae* (e.g., California encephalitis virus),
30 *Arenaviridae* (e.g., Lymphocytic choriomeningitis virus), *Retroviridae* (e.g., *HIV-1*), and *Hepadnavirida* (e.g., Hepatitis B). The emulsions of the invention can also be used to inactivate viruses in vitro, for example, to disinfect contaminated blood products. In a preferred embodiment of the invention, the oil-in-water emulsions are used to inactivate HIV.

35 The present invention also provides an antimicrobial preparation suitable for pharmaceutical administration consisting of the antimicrobial emulsion of the present invention and a pharmaceutically acceptable carrier. The term "pharmaceutically acceptable carrier," as used herein, refers to any physiologically compatible carrier for use in pharmaceutical administration. Use of such media and agents for pharmaceutically active

substances is well known in the art. Except insofar as any conventional media or agent is incompatible with the emulsions of the present invention, use thereof in a pharmaceutical preparation is contemplated.

5 The present invention further provides methods for inhibiting the growth of an infectious pathogen by topical, or systemic administration of the antimicrobial emulsion of the present invention, preferably in the form of a pharmaceutical preparation. The term "topical," as used herein, includes application to mucous membranes, oral surfaces, skin, inner ear surfaces, or the surfaces of any bodily orifice, such as the vagina or rectum. The
10 term "systemic", as used herein, includes any form of internal administration, including but not limited to, oral and intravenous administration.

The following examples will illustrate the efficacy of the invention.

15

EXAMPLES

Example 1 - Preparation of GMO and GMS Oil-in-Water Emulsions

20 In this Example, a series of positively and negatively charged lipid-containing oil-in-water emulsions having either GMO or GMS as the primary emulsifier were formed. Selected emulsions were also characterized with regard to purity, pH and size of oil droplets.

25 Table 1 shows the amount of each chemical component used to form the lipid-oil phase of several charged GMO and GMS oil-in-water emulsions having glycerol monooleate (GMO) or glycerol monostearate (GMS) as the primary emulsifiers, and cetylpyridinium chloride (CPC), cetylpyridinium bromide (CPB), cetyltrimethylammonium bromide (CTAB), or dimethyldioctadecylammonium bromide (DDDAB) as positive charge producing agents, or oleic acid as a negative charge producing agent.

TABLE 1

	GMO/ CPC	GMO/ CPB	GMO/ CTAB	GMS/ DDDAB	GMO/ OLEIC	GMS/ CPC
GMO	3.43 g	3.43 g	3.43 g	-----	3.43 g	-----
GMS	-----	-----	-----	3.43 g	-----	3.43 g
Soya Sterol or cholesterol	0.96 g	0.96 g	0.96 g	0.96 g	0.96 g	0.96 g
Tween 60	0.84 g	0.84 g	0.84 g	0.84 g	0.84 g	0.84 g
Soybean Oil	11 g	11 g	11 g	11 g	11 g	11 g
CPC	130 mg	-----	-----	-----	-----	130 mg
CPB	-----	150 mg	-----	-----	-----	-----
CTAB	-----	-----	140 mg	-----	-----	-----
DDDAB	-----	-----	-----	240 mg	-----	-----
Oleic Acid	-----	-----	-----	-----	108 mg	-----

To prepare the charged emulsions shown above in Table 1, a lipid-oil phase containing approximately 12 to 21% by weight GMO or GMS, 0.8 to 0.9% by weight cationic halogen-containing compound (or 0.7% by weight oleic acid), 67 to 80% by weight carrier oil such as soybean oil, 3 to 5% by weight Tween 60 (Polyoxyethylene 20 sorbitan monostearate), and 3 to 6% by weight soya sterol was heated for approximately one hour at 86°C. The lipid-oil phase was then blended with an aqueous phase containing water at 65°C using a 5 ml syringe machine as described in US Patent No. 4,895,452 on a volume to volume basis of 13 parts lipid-oil to 37 parts water.

Table 2 shows the pH of the emulsions shown in Table 1. Also shown is the size of the lipid-oil droplets of the emulsions measured on a Coulter LS 130 Laser sizing instrument equipped with a circulating waterbath.

15

TABLE 2

Chemical Components of Emulsion	Charge	pH	Mean Coulter Size in Microns	Mean Coulter Range in Microns
GMO/CPC	Positive	3.72	1.049	0.720-1.401
GMO/CPB	Positive	4.31	0.891	0.680-1.124
GMO/CTAB	Positive	4.82	1.143	0.647-1.358
GMS/DDDAB	Positive	5.86	1.080	0.694-1.532
GMO/Oleic acid	Negative	4.45	1.078	0.738-1.448
GMS/CPC	Positive	3.72	1.047	0.677-1.497

Example 2 - Preparation of 10N GMO Oil-in-Water Emulsions

In this Example, a series of positively charged oil-in-water emulsions were prepared having GMO as the primary emulsifier and a 10 fold higher percentage (10N) of cationic halogen-containing compound (cetylpyridinium chloride (CPC), cetylpyridinium bromide (CPB), cetyltrimethylammonium bromide (CTAB), cetyldimethylethylammonium bromide (CDEAB), and benzalkonium chloride (BAC)), as compared with Example 1, as a positive charge producing agent.

Table 3 shows the amount of each chemical component used to form the lipid-oil phase of the positively charged 10N GMO emulsions.

TABLE 3 Positively Charged 10N Emulsions

Chemical Components of Emulsion	GMO/ CPC	GMO/ CPB	GMO/ CTAB	GMO/ CDEAB	GMO/ BAC
GMO	3.43 g	3.43 g	3.43 g	3.43g	3.43 g
Soya Sterol or cholesterol	0.96 g	0.96 g	0.96 g	0.96 g	0.96 g
Tween 60	0.84 g	0.84 g	0.84 g	0.84 g	0.84 g
Soybean Oil	11 g	11 g	11 g	11 g	11 g
CPC	1.3 g	-----	-----	-----	-----
CPB	-----	1.5 g	-----	-----	-----
CTAB	-----	-----	1.4 g	-----	-----
CDEAB	-----	-----	-----	1.3 g	-----
BAC	-----	-----	-----	-----	1.3 g

To prepare the 10N emulsions shown above in Table 3, a lipid-oil phase containing approximately 19% by weight GMO, 62% by weight carrier oil such as soybean oil, 4.7% by weight Tween 60 (Polyoxyethylene 20 sorbitan monostearate), 5.4% by weight soya sterol, and 7.4 to 8.4% by weight cationic detergent was heated for approximately one hour at 86°C. The lipid-oil phase was then blended with an aqueous phase containing water at 65°C using a 5 ml syringe machine (as described in U.S. Patent No. 4,895,452, the teachings of which are incorporated by reference herein) on a volume to volume basis of 13 parts lipid-oil to 37 parts water.

Example 3 - Microbicidal Activity of GMO and GMS Oil-in-Water Emulsions
Against *Staphylococcus aureus* type 8

In this Example, the microbicidal activities of each of the GMO and GMS emulsions shown in Table 1 were compared. For this purpose, the ability of each of the emulsions to
 5 kill *Staphylococcus aureus* type 8 was tested as follows:

Bacteria were inoculated into liquid media (Trypticase soy broth or Schaedler's broth) and incubated at 37°C for 1-7 hours. An optical density at a wavelength of 650 nm and a quantitative culture were then performed on each broth culture. One milliliter of each
 10 bacterial broth was then mixed with one milliliter of emulsion, or water as a control, for 10 or 30 minutes. Quantitative cultures were then performed in duplicate on each mixture. Plates containing bacteria were incubated at 37°C for 18 hours and then counted.

The percentage of bacteria killed was then determined by the following equation.

$$15 \quad \% \text{ kill} = \frac{(A - B)}{A} \times 100$$

A = The total number of bacteria inoculated

B = The total number counted after mixing with an emulsion
 20

Table 4 lists the percentages of *Staphylococcus aureus* type 8 killed by each emulsion or water after a 10 or 30 minute incubation with 2×10^7 bacteria.

TABLE 4

Chemical Components of Preparation	% Inactivate After a 10 Minute Incubation	% Inactivate After a 30 Minute Incubation
GMO/CPC	100	100
GMO/CPB	100	100
GMO/CTAB	99.99	99.99
GMO/DDDAB	65	0
GMO/Oleic acid	0	0
GMS/CPC	65	0
Control alone	50	0

25

From Table 4 one can see that the positively charged glycerol monooleate (GMO) emulsions inactivate *Staphylococcus aureus* type 8 while the positively charged glycerol monostearate (GMS/CPC) emulsion fails to inactivate. In addition, only the cationic compounds having a C₁₂-C₁₆ chain containing either chloride or bromide, i.e., CPC, CPB or

CTAB, and not the dioctadecyl cationic compound (DDDAB) or oleic acid (having a negative charge), were associated with significant microbicidal activity. The inactivation of this bacterium, *Staphylococcus aureus*, is therefore more effective using GMO emulsions containing a chloride or bromide containing cationic compound having a C₁₂-C₁₆ chain.

5 In order to determine the effect of varying the concentration of the charge producing agent in the emulsions of the invention, GMO emulsions containing different concentrations of CPC were also tested for antimicrobial activity against *Staphylococcus aureus* type 8. Table 5 shows percentages of *Staphylococcus aureus* type 8 killed after a 10 or 30 minute
10 incubation of the GMO emulsions with 10⁷ bacteria.

TABLE 5

Chemical Components of Emulsion	Initial Inoculum of Staphylococcus Aureus Type 8	% Inactivate After a 10 Minute Incubation	% Inactivate After a 30 Minute Incubation
GMO/CPC	10,000,000 CFU [1.8 mg/ml emulsion]	100	100
GMO/CPC	10,000,000 CFU [0.9 mg/ml emulsion]	99.5	100
GMO/CPC	10,000,000 CFU [0.45 mg/ml emulsion]	54	99.5
GMO/CPC	10,000,000 CFU [0.23 mg/ml emulsion]	39	32
GMO/CPC	10,000,000 CFU [0.028 mg/ml emulsion]	0	0
GMO	10,000,000 CFU	0	0
GMO/Oleic acid	10,000,000 CFU	0	0
Water alone	10,000,000 CFU	10	0

Table 5 demonstrates that *Staphylococcus aureus* type 8 bacteria were sensitive to the microbicidal action of the GMO/CPC emulsion at CPC concentrations of greater than 0.23 mg/ml of emulsion.

5

Example 4 - Microbicidal Activity of GMO Oil-in-Water Emulsions Against Bacteria and Yeast

In this Example, the ability of the GMO/CPC emulsion formed in Example 1 and shown in Table 1 to kill a variety of bacteria and yeast was tested.

10

The assay described above in Example 3 was used to measure the microbicidal activity of the GMO/CPC emulsion against a number of bacteria and fungi, except for the following changes:

15

Yeast were inoculated into Sabouraud's broth and incubated at 30°C for 6 hours, mixed with the GMO/CPC emulsion for 10 or 30 minutes, plated and incubated at 37 C for 18 hours before counting.

20

P. acnes was grown anaerobically in Schaedler's broth for 24 hours, mixed with emulsion for 10 or 30 minutes, plated on Trypticase soy agar plates with 5% sheep blood and incubated anaerobically for 72 hours prior to counting.

25

G. vaginalis was plated on Trypticase soy agar plates with 5% sheep blood and incubated in 5% CO₂ at 37°C for 72 hours. Colonies were swabbed from plates and inoculated into Schaedler's broth at the density of a 0.5 McFarland standard. This broth/bacterial mixture was then incubated with the emulsion for 10 or 30 minutes and then plated on Trypticase soy agar plates with 5% sheep blood. Plates were incubated for 72 hours in 5% CO₂ at 37°C before counting colonies.

30

Table 6 lists the percentage of gram positive bacteria killed after a 10 or 30 minute incubation of the GMO/CPC emulsion with between 10⁵ and 10⁸ bacteria. The listed bacteria can generally be categorized as follows: (a) those which colonize on the skin which include *Staphylococcus aureus* (type 8), *Staphylococcus aureus* (type 5), *Staphylococcus epidermidis* (strain 977), Group B *Streptococcus* (capsular type III), Group A *Streptococcus* (beta-hemolytic), and *Propionibacterium acnes*; (b) those which colonize in the oropharynx which include Group A *Streptococcus* (beta-hemolytic), *Streptococcus pneumoniae* (type 5), and *Streptococcus mutans*; and (c) those which colonize or infect the vagina which include *Gardnerella vaginalis* and Group B *Streptococcus* (capsular type III).

35

TABLE 6

	Innoculum (CFU)•	% Inactivate after a 10 Minute Incubation	% Inactivate after a 30 Minute Incubation
Gram Positive Bacteria			
<i>Staphylococcus aureus</i> (type 8/bacteremic isolate)	2×10^7	99.99	99.99

Group B <i>Streptococcus</i> (capsular type III)	2.9×10^7	99.99	100
Group A beta-hemolytic (type 1) <i>Streptococcus</i> (ATCC 12344)	3.3×10^7	99.99	99.99
<i>Listeria monocytogenes</i> (type 2) (ATCC 19112)	1.3×10^8	99.99	99.99
<i>Streptococcus pneumoniae</i> (type 5) (ATCC 6305)	6.4×10^7	100	100
<i>Streptococcus mutans</i> (ATCC 25179)	6.5×10^6	96.2	96.8
<i>Propionibacterium acnes</i> (ATCC 6919)	1.2×10^8	100	100
<i>Enterococcus fecalis</i> (ATCC 19433)	3.7×10^7	99.36	99.98
<i>Gardnerella vaginalis</i> (ATCC 14018)	5.5×10^7	100	100
<i>Lactobacillus acidophilus</i> (ATCC 4356)	5.0×10^5	100	100

• CFU = colony forming units

Table 6 demonstrates that all gram positive bacteria which cause significant human clinical infections were exquisitely sensitive to the microbicidal action of the GMO/CPC emulsion.

Table 7 shows the percentage of gram negative bacteria killed after a 10 or 30 minute incubation of the GMO/CPC emulsion with between 10^5 and 10^8 bacteria. Included in the table are gram negative bacteria which colonize in the oropharynx, such as *Haemophilus*

influenzae (capsular type b) and *Neisseria meningitidis* type b; the gastrointestinal tract, such as *Helicobacter pylori*; and the vagina, such as *Neisseria gonorrhoeae*.

TABLE 7

		% Inactivate after a 10 Minute Incubation	% Inactivate after a 30 Minute Incubation
Gram Negative Bacteria	Innoculum (CFU)•		
<i>Escherichia coli</i> type O18:K1	2.1×10^7	97.1	96.7
<i>Escherichia coli</i> type O18:K-	3.2×10^7	89.7	99.6
<i>Escherichia coli</i> J5 (epimerase deficient)	3×10^7	94	85
<i>Flavobacterium meningosepticum</i> Group A (ATCC 13253)	2.1×10^6	0	47.6
<i>Klebsiella pneumonia</i> type O12K+	5×10^7	98.3	99.9
<i>Pseudomonas aeruginosa</i> type FD-1	3.8×10^7	99	99
<i>Pseudomonas aeruginosa</i> MEP strain 2192	8×10^6	99.1	97.5
<i>Haemophilus influenzae</i> capsular type b (ATCVC 33533)	1×10^7	99.99	99.99
<i>Neisseria meningitidis</i> type b (ATCC 13090)	1.6×10^8	100	100
<i>Neisseria gonorrhoeae</i> (ATCC 9793)	1.2×10^6	100	100
<i>Helicobacter pylori</i> (ATCC 43504)	3×10^6	100	100
<i>Helicobacter pylori</i> (ATCC 43629)	4.7×10^6	100	100
<i>Helicobacter pylori</i> (ATCC 49503)	2×10^6	100	100
<i>Helicobacter pylori</i> (ATCC 43579)	7×10^6	100	100

5

Table 7 illustrates that at 30 minutes there is inactivation of at least 85% of the innoculum of all gram negative bacteria tested except for *Flavobacterium meningosepticum*. The encapsulated type b *Haemophilus influenzae*, type b *Neisseria meningitidis*, *Neisseria gonorrhoeae*, and *Helicobacter pylori* bacteria, which have relatively rough LPS types compared to the other gram negative bacteria, are exquisitely sensitive to the microbicidal activity of the GMO/CPC emulsion.

10

Table 8 shows the percentage of the two *Candida* species killed after a 10 or 30 minute incubation of the GMO/CPC emulsion with 10^5 yeast.

TABLE 8

Yeast	Innoculum (CFU)	% Inactivate After a 10 Minute Incubation	% Inactivate After a 30 Minute Incubation
<i>Candida albicans</i> (clinical blood isolate)	3.2×10^5	62.5	62.5
<i>Candida tropicalis</i> (clinical blood isolate)	5.4×10^5	100	100

Table 8 demonstrates that significant inactivating of the *Candida albicans* species occurs after only a 10-30 minute incubation with the GMO/CPC emulsion.

10 **Example 5 - Microbicidal Activity of 10N GMO Emulsions**

In this Example, the positively charged 10N GMO emulsions formed in Example 2 and shown in Table 3 were tested for microbicidal activity against two gram positive bacteria, *Staphylococcus aureus* type 8 and *Staphylococcus epidermidis*, and two gram negative bacteria, *E. coli* and *Helicobacter pylori*, as follows:

15 To lyophilized cultures of bacteria, 0.5 mL of Schaedler's Broth was added and the entire contents of the vial inoculated to a 5% Sheep blood agar plate (TSA II). Cultures were then incubated in an anaerobic jar with Campy GasPAK at 37°C for 72 hours. Colonies from 72 hour TSA II plates were then innoculated into Schaedler's broth until an 0.5 McFarland
20 Standard was achieved.

A one ml aliquot of the bacterial culture was then mixed with one ml of oil-in-water emulsion for 10 minutes. Quantitative cultures were then performed in duplicate on each mixture, and a quantitative culture was performed on the original broth culture. Plates
25 containing bacteria were incubated at 37°C for 72 hours in an anaerobic jar with Campy GasPaks and then counted. The percentage of bacteria killed were determined by the following equation and the results are shown in Table 9:

$$\% \text{ Kill} = \frac{(A-B)}{A} \times 100$$

30

A

A = The total number of bacteria inoculated

B = The number counted after mixing with an emulsion or liposomes

5 Table 9 lists the percentages of each bacterium killed after a 10 minute incubation with the 10N GMO/CPC emulsion from Table 3 with between 10^6 and 10^7 bacteria. The 10N GMO/CPC emulsion was tested in undiluted form and in several dilutions, as indicated in Table 9.

10 **TABLE 9**

Bacterium	Dilution	Trial # 1	Trial # 2
<i>Staphylococcus aureus</i>	Undilute	NT	100.00%
Type 8	1 : 10		99.99%
8 x 10^7 CFU/mL	1 : 20		99.99%
10 minute incubation	1 : 40		99.99%
	1 : 80		96.25%
<i>Staphylococcus epidermidis</i> 977	Undilute	NT	100.00%
	1 : 10		100.00%
9 X 10^6 CFU/mL	1 : 20		100.00%
10 minute incubation	1 : 40		99.98%
	1 : 80		99.97%
<i>Escherichia coli</i>	Undilute	NT	99.99%
Type 02a,2b	1 : 10		99.99%
1 X 10^7 CFU/mL	1 : 20		99.98%
10 minute incubation	1 : 40		94.00%
	1 : 80		50.00%
<i>Helicobacter pylori</i> 43579	Undilute	100.00%	100.00%
10 minute incubation	1 : 10	100.00%	100.00%
Inoculum for Trial #1	1 : 20	100.00%	100.00%
5X 10^6 CFU/ml			
Inoculum for Trial #2	1 : 40	99.00%	99.00%
2X 10^7 CFU/ml			
	1 : 80	99.20%	99.00%

NT = Not Tested on This Date

15 Table 9 shows that at 10 minutes there is a greater than 96% inactivation of each bacterium (except for *E. coli* at high dilutions (i.e., 1 : 40 and 1 : 80)) tested with the 10N

GMO/CPC emulsion up to a 1 : 80 dilution. At a dilution of 1 : 10, there is a 99.99-100% inactivation of each bacterium.

5 **Example 6 - Viricidal Activity of GMO Oil-in-Water Emulsions and Fusogenic Lipid Vesicles Against HIV**

In this Example, the viricidal activity of the GMO/CPC emulsion formed in Example 1 and fusogenic lipid vesicles prepared as described below were tested against HIV.

10 To prepare fusogenic lipid vesicles, 94.5 grams of Polyoxyethylene (POE) 2 Stearyl Ether (Brij 72), 0.78 grams of oleic acid, and 36 grams of cholesterol were heated to melting to form a liquid lipid phase. A portion of that lipid phase, 0.53 ml, was then mixed with 0.47 ml of squalene to form 1.0 ml of a lipid-oil phase. This was blended with an aqueous phase containing 4.0 ml of PBS under shear mixing conditions to form the lipid vesicles, as
15 described in U.S. Patent 4,911,928. "Shear mixing conditions", as used herein, means a shear equivalent to a relative flow of 5-50 m/s through a 1mm orifice. On a volume to volume basis, the mixture contained 4 parts diluent to 1 part lipid-oil mixture, or 11.7% lipid to 8.3% oil to 80% diluent.

20 The GMO/CPC emulsion and Brij 72 fusogenic lipid vesicles were assayed for viricidal activity against HIV as follows:

 A cell suspension containing 20×10^6 C8166 cells, a HTLV-1 transformed T cell line, in 20 ml of RPMI media containing 10% PBS and 50 $\mu\text{g/ml}$ gentamicin was prepared
25 and divided into 0.4 ml aliquots. A series of viral dilutions (10^{-2} to 10^{-6}) were then made by first mixing 100 microliters of HIV-1_{Mn} 1000 x pelleted virus with either 100 microliters of sterile water or 100 microliters of the GMO/CPC emulsion for 30 minutes at room temperature on a nutator. 1.8 ml of tissue culture medium was then added to each preparation, resulting in a dilution of 10^{-1} . Serial 10-fold dilutions were then performed from
30 10^{-2} to 10^{-6} by taking 150 microliters of the 10^{-1} dilution and serially diluting it out in 1.35 ml of RPMI media five more times.

 Two 0.4 ml aliquots of each dilution were then added to the aliquots of C8166 cells, prepared as described above. The samples were incubated at 37°C for either 2, 6 or 24 hours,
35 washed 3 times in phosphate buffered saline, resuspended in fresh medium and each dilution plated in four replicate wells. Cells were fed twice weekly. Cells were observed at 7 and 14 days for cytopathic effects and supernatants were collected to measure levels of p24 as an indication of viral proliferation. Tissue culture infectious dose (TCID₅₀ (\log_{10})) calculations were then performed based on the measured levels of p24. The results were as follows:

For samples incubated for 2 hours with the GMO/CPC emulsion, there was a 4.5 log virus reduction, as compared with water, in the TCID-50 at 7 days and a 4.25 log virus reduction in the TCID-50 at 14 days.

5

For samples incubated for 6 hours with the GMO/CPC emulsion, there was a 4.5 log virus reduction, as compared with water, in the TCID-50 at 7 days and a 5 log virus reduction, as compared with water, in the TCID-50 at 14 days.

10

For samples incubated for 24 hours with the GMO/CPC emulsion, there was a 4.0 log virus reduction, as compared with water, in the TCID-50 at 7 and 14 days; there was a 3.75 and 4.25 log reduction, as compared with Phosphate Buffered Saline, in the TCID-50 at 7 and 14 days, respectively; and there was a 4.0 and 4.5 log reduction, as compared with fusogenic novasomes containing POE 2 Stearyl Ether, in the TCID-50 at 7 and 14 days, respectively.

15

Overall, this Example demonstrates that GMO/CPC emulsions inactivate 4.0 to 5.0 logs of HIV-1_{Mn} infectivity in C8166 tissue culture assays. These experiments, which can be performed using any enveloped virus, demonstrate the effectiveness of these materials to inactivate viruses such as HIV-1_{Mn}.

20

Example 7 - Stability of GMO Oil-in-Water Emulsions

In this Example, the GMO/CPC emulsion formed in Example 1 was tested for stability in the presence of heat, acid and base. Table 10 shows the effect of boiling for one hour on breakdown or aggregation of the GMO/CPC emulsion, shows the effects of mixing equal volumes of 1N Nitric acid and GMO/CPC emulsion for two hours on breakdown or aggregation of the GMO/CPC emulsion, and the effects of mixing equal volumes of 1N Sodium hydroxide and GMO/CPC emulsion for two hours on breakdown or aggregation of the GMO/CPC emulsion.

25

TABLE 10

Chemical Components of Emulsion	Intervention	Mean Coulter Size in Microns	Mean Coulter Range in Microns
GMO/CPC	No boiling	1.008	0.720-1.337
GMO/CPC	Boiling 1 hour	1.167	0.654-1.517
GMO/CPC	No acid treatment	1.008	0.720-1.337
GMO/CPC	1N HNO ₃ for 2 hours	1.062	0.675-1.569
GMO/CPC	No base treatment	1.008	0.720-1.337
GMO/CPC	1N NaOH for 2 hours	0.804	0.658-0.969

Table 10 shows that : (a) boiling for 1 hour does not significantly alter the breakdown or size of the emulsion; (b) 1N Nitric acid exposure for 2 hours does not significantly alter the size or aggregate profile of the CMO/CPC emulsion; and (c) 1N Sodium hydroxide exposure for 2 hours causes a 20% decrease in the mean size of the emulsion without disrupting the emulsion or causing aggregation.

From the above-described Examples 1-7, it is evident that the antimicrobial oil-in-water emulsions of the present invention have significant microbicidal activity against a wide variety of viruses, bacteria and yeast, even at extremely low concentrations of cationic halogen-containing compound, such as CPC. Furthermore, the emulsions of the invention are stable in the presence of heat, acid, and base, making them very suitable for pharmaceutical administration, whether topical, oral or systemic.

Those skilled in the art will recognize, or be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described herein. Such equivalents are intended to be encompassed by the following claims.

What is claimed is:

1. An antimicrobial oil-in-water emulsion comprising positively charged droplets of an oily discontinuous phase dispersed in a continuous aqueous phase, the emulsion comprising:
 - a. an oil;
 - b. a glycerol ester; and
 - c. a cationic halogen-containing compound having a C₁₂-C₁₆ chain.
2. An antimicrobial emulsion of claim 1, wherein the glycerol ester is selected from the group consisting of glycerol monooleate, glycerol trioleate, glycerol monolaurate, and glycerol dilaurate.
3. An antimicrobial emulsion of claim 1, wherein the oil is selected from the group consisting of soybean oil, squalene oil, sesame oil, olive oil, canola oil, corn oil, rapeseed oil, safflower oil, sunflower oil, fish oils, avocado oil, flavor oils, water insoluble vitamins, and mixtures thereof.
4. An antimicrobial emulsion of claim 1, wherein the halogen is selected from the group consisting of bromine, chlorine, and fluorine.
5. An antimicrobial emulsion of claim 1, wherein the cationic halogen-containing compound having a C₁₂-C₁₆ chain is selected from the group consisting of cetylpyridinium chloride, cetylpyridinium bromide, cetyltrimethylammonium bromide, cetyltrimethylammonium chloride, cetyldimethylethylammonium bromide, cetylbenzyltrimethylammonium chloride, cetyltributylphosphonium bromide, dodecyltrimethylammonium bromide, and tetradecyltrimethylammonium bromide.
6. An antimicrobial emulsion of claim 1, wherein the emulsion further comprises at least one sterol selected from the group consisting of cholesterol, cholesterol derivatives, hydrocortisone, phytosterol, and mixtures thereof.
7. The antimicrobial emulsion of claim 1, wherein at least a portion of the emulsion is in the form of a positively charged lipid structure selected from the group consisting of unilamellar, multilamellar, and paucilamellar lipid vesicles, micelles, and lamellar phases.
8. An antimicrobial preparation suitable for pharmaceutical administration comprising the antimicrobial emulsion of claim 1 and a pharmaceutically acceptable carrier.

9. An antimicrobial oil-in-water emulsion comprising positively charged droplets of an oily discontinuous phase dispersed in a continuous aqueous phase, the emulsion comprising:

- a. an oil selected from the group consisting of soybean oil, squalene oil, squalane oil, sesame oil, olive oil, canola oil, corn oil, rapeseed oil, safflower oil, sunflower oil, fish oils, avocado oil, flavor oils, water insoluble vitamins, and mixtures thereof;
- b. glycerol monooleate; and
- c. cetylpyridinium chloride.

10. An antimicrobial preparation suitable for pharmaceutical administration comprising the antimicrobial emulsion of claim 9 and a pharmaceutically acceptable carrier.

11. A method of inhibiting the growth of an infectious pathogen comprising the step of topical application of an antimicrobial oil-in-water emulsion, said antimicrobial emulsion being in the form of positively charged droplets of an oily discontinuous phase dispersed in a continuous aqueous phase, the emulsion comprising:

- a. an oil;
- b. a glycerol ester; and
- c. a cationic halogen-containing compound having a C₁₂-C₁₆ chain.

12. The method of claim 11, wherein the glycerol ester is selected from the group consisting of glycerol monooleate, glycerol trioleate, glycerol monolaurate, and glycerol dilaurate as the primary emulsifier.

13. The method of claim 11, wherein the halogen is selected from the group consisting of bromine, chlorine, and fluorine.

14. The method of claim 11, wherein the cationic halogen-containing compound having a C₁₂-C₁₆ chain is selected from the group consisting of cetylpyridinium chloride, cetylpyridinium bromide, cetyltrimethylammonium bromide, cetyldimethylethylammonium bromide, and benzalkonium chloride.

15. The method of claim 11, wherein the oil is selected from the group consisting of soybean oil, squalene oil, sesame oil, olive oil, canola oil, corn oil, rapeseed oil, safflower oil, sunflower oil, fish oils, avocado oil, flavor oils, water insoluble vitamins, and mixtures thereof.

16. The method of claim 11, wherein the emulsion further comprises at least one sterol selected from the group consisting of cholesterol, cholesterol derivatives, hydrocortisone, phytosterol, and mixtures thereof.

5 17. The method of claim 11, wherein said topical application comprises oral application.

18. The method of claim 11, wherein said topical application comprises application to a mucous membrane via inhalation.

10

19. The method of claim 11, wherein said topical application comprises vaginal application.

15

20. The method of claim 11, wherein the infectious pathogen is a bacterium.

21. The method of claim 11, wherein the infectious pathogen is a fungus.

22. The method of claim 11, wherein the infectious pathogen is a virus.

20

23. The method of claim 22, wherein the virus is an enveloped virus.

24. The method of claim 23, wherein the enveloped virus is HIV.

25 25. The method of claim 23, wherein the enveloped virus is selected from the group consisting of *Herpesviridae*, *Togaviridae*, *Flaviviridae*, *Coronaviridae*, *Rhabdoviridae*, *Filoviridae*, *Paramyxoviridae*, *Orthomyxoviridae*, *Bunyaviridae*, *Arenaviridae*, *Retroviridae*, and *Hepadnavirida*.

30 26. A method of inhibiting the growth of an infectious pathogen comprising the step of topical application of an antimicrobial oil-in-water emulsion to an area containing the infectious pathogen, the antimicrobial emulsion being in the form of positively charged droplets of an oily discontinuous phase dispersed in a continuous aqueous phase, the emulsion comprising:

- 35 a. an oil selected from the group consisting of soybean oil, squalane oil, sesame oil, olive oil, canola oil, corn oil, rapeseed oil, safflower oil, sunflower oil, fish oils, avocado oil, flavor oils, water insoluble vitamins, and mixtures thereof;
- b. glycerol monooleate; and
- c. cetylpyridinium chloride.

27. A method of inhibiting the growth of an infectious pathogen *in vivo* comprising the step of systemically administering to a subject an antimicrobial oil-in-water emulsion, said antimicrobial emulsion being in the form of positively charged droplets of an oily discontinuous phase dispersed in a continuous aqueous phase, the emulsion comprising:

- a. an oil selected from the group consisting of soybean oil, squalene oil, sesame oil, olive oil, canola oil, corn oil, rapeseed oil, safflower oil, sunflower oil, fish oils, avocado oil, flavor oils, water insoluble vitamins, and mixtures thereof;
- b. a glycerol ester selected from the group consisting of glycerol monooleate, glycerol trioleate, glycerol monolaurate, and glycerol dilaurate; and
- c. a cationic halogen-containing compound having a C₁₂-C₁₆ chain selected from the group consisting of cetylpyridinium chloride, cetylpyridinium bromide, cetyltrimethylammonium bromide, cetyldimethylethylammonium bromide, and benzalkonium chloride.

28. The method of claim 27, wherein the emulsion further comprises at least one sterol selected from the group consisting of cholesterol, cholesterol derivatives, hydrocortisone, phytosterol, and mixtures thereof.

29. The method of claim 27 wherein said step of systemically administering comprises enteral administration.

30. The method of claim 27, wherein the pathogen is selected from the group consisting of bacteria, fungi, and viruses.

31. A method of treating an infection by a pathogen in a subject comprising the step of systemically administering to the subject an antimicrobial oil-in-water emulsion comprising positively charged droplets of an oily discontinuous phase dispersed in a continuous aqueous phase, the emulsion comprising:

- a. an oil;
- b. glycerol monooleate; and
- c. cetylpyridinium chloride.

32. A method of inactivating an infectious pathogen *in vitro* comprising the step of contacting the pathogen with an antimicrobial oil-in-water emulsion, the emulsion being in the form of positively charged droplets of an oily discontinuous phase dispersed in a continuous aqueous phase, the emulsion comprising:

- a. an oil selected from the group consisting of soybean oil, squalene oil, sesame oil, olive oil, canola oil, corn oil, rapeseed, safflower oil, sunflower oil, fish oils,

petrolatum, avocado oil, triglyceride oils and fats, flavor oils, water insoluble vitamins, and mixtures thereof;

b. a glycerol ester selected from the group consisting of glycerol monooleate, glycerol trioleate, glycerol monolaurate, and glycerol dilaurate; and

5 c. a cationic halogen-containing compound having a C₁₂-C₁₆ chain selected from the group consisting of cetylpyridinium chloride, cetylpyridinium bromide, and cetyltrimethylammonium bromide.

10 33. The method of claim 32, wherein the pathogen is a virus.

34. The method of claim 33, wherein the virus is HIV.

(54) Title: TARGETED HETERO-ASSOCIATION OF RECOMBINANT PROTEINS TO MULTI-FUNCTIONAL COMPLEXES (57) Abstract The present invention relates to a method for targeted assembly of distinct active peptide or protein domains into a single complex and to such complexes. The invention relates particularly to the fusion of peptide or protein domains to complementary association domains which are derived from a single tertiary or quaternary structure by segmentation. The association domains are designed to assemble in a complementary fashion, thereby providing multifunctional (poly)peptides.

TARGETED HETERO-ASSOCIATION OF RECOMBINANT PROTEINS TO MULTI-FUNCTIONAL COMPLEXES

Background of the Invention

Increasingly, there is a need for proteins which combine two or more functions, such as binding or catalysis, in a single structure. Typically, proteins which combine two or more functions are prepared either as fusion proteins or through chemical conjugation of the component functional domains. Both of these approaches suffer from disadvantages. Genetic "single chain" fusions suffer the disadvantages that (i) only a few (2-3) proteins can be fused (Rock et al., 1992, *Prot. Eng.* 5, 583-591), (ii) mutual interference between the component domains may hinder folding, and (iii) the size of the fusion protein may make it difficult to prepare. The alternative, chemical cross-linking *in vitro* following purification of independently expressed proteins, is difficult to control and invariably leads to undefined products and to a severe loss in yield of functional material.

Recently, methods for achieving non-covalent association of two or more of the same functional domains have been developed. This can be achieved through the use of domains attached to peptides which self-associate to form homo-multimers (Pack & Plückthun, 1992, *Biochemistry* 31, 1579-1584). For example, the association of two separately expressed scFv antibody fragments by C-terminally fused amphipathic helices *in vivo* provides homo-dimers of antibody fragments in *E. coli* (PCT/EP93/00082; Pack et al., 1993, *Bio/Technology* 11, 1271-1277) or homo-tetramers; (Pack et al., 1995, *J. Mol. Biol.*, 246, 28-34).

To assemble distinct protein functions such as two antibody fragments with different specificities fused to such association domains, the helices must have a tendency to form hetero-multimers. In principle, this could be achieved with complementary helices such as the hetero-dimerizing JUN and FOS zippers of the AP-1 transcription factor (O'Shea et al., 1992, *Cell* 68, 699-708). The clear disadvantage of association domains based on hetero-associating helices,

however, is their pseudo-symmetry and their similar periodicity of hydrophobic and hydrophilic residues. This structural similarity results in a strong tendency to form homo-dimers and, thus, to lower significantly the yield of hetero-dimers (O'Shea et al., 1992, *Cell* 68, 699-708; Pack, 1994, Ph. D. thesis, Ludwig-Maximilians-Universität München). Furthermore, the formation of JUN/FOS hetero-dimers is kinetically disfavoured and requires a temperature-dependent unfolding of the kinetically favoured homo-dimers, especially JUN/JUN homo-dimers (PCT/EP93/00082; O'Shea et al., 1992, *Cell* 68, 699-708; Pack, 1994, Ph. D. thesis, Ludwig-Maximilians-Universität München). Because of the need for additional purification steps to separate the unwanted homo-dimers from hetero-dimers and the resulting decrease in yield, hetero-association domains based on amphipathic helices do not result in practical advantages compared to conventional chemical coupling.

These disadvantages of the prior art are overcome by the present invention which provides multi-functional polypeptides and methods for the preparation of these multi-functional proteins. This is achieved via the use of association domains which are designed to associate predominantly in a complementary fashion, and not to self-associate.

Detailed Description of the Invention

In the earliest steps of protein folding, peptide chains form a disordered hydrophobic core by collapsing hydrophobic residues into the interior of an intermediate "molten globule". This hydrophobic effect is considered to be the most important driving force of folding (Matthews, 1993, *Annu. Rev. Biochem.* 62, 653 - 683; Fersht, 1993, *FEBS Letters* 325, 5 - 16). The burial of hydrophobic residues and the resulting exclusion of solvent is the determining factor in the stability of compact tertiary structures such as acyl-phosphatase (Pastore et al, J. Mol. Biol. 224, 427-440, 1992) interleukin-2 (Brandhuber et al., 1987, *Science* 238, 1707 - 1709), calbindin (Parmentier, 1990, *Adv. Exp. Med. Biol.* 269, 27-34) or ubiquitin (Briggs & Roder, 1992, *Proc. Natl. Acad. Sci. USA* 89, 2017 - 2021).

This concept forms the basis of the present invention, which provides individually encoded peptides or "segments" which, in a single continuous chain, would comprise a compact tertiary structure with a highly hydrophobic core. The component peptides are chosen so as to be asymmetric in their assumed structure, so as not to self-associate to form homo-multimers, but rather to associate in a complementary fashion, adopting a stable complex which resembles the parent tertiary structure. On the genetic level, these segments are encoded by interchangeable cassettes with suitable restriction sites. These standardized cassettes are fused C- or N-terminally to different recombinant proteins via a linker or hinge in a suitable expression vector system.

Thus, the present invention relates to a multi-functional polypeptide comprising:

- (a) a first amino acid sequence attached to at least one functional domain;
- (b) a second amino acid sequence attached to at least one further functional domain; and
- (c) optionally, further amino acid sequences each attached to at least one further functional domain;

wherein any one or more of said amino acid sequences interacts with at least one of said amino acid sequences in a complementary fashion to form a parental, native-like tertiary or optionally quaternary structure and wherein the parental, native-like tertiary or optionally quaternary structure is derived from a single parent polypeptide. In this context, the term parent polypeptide refers to a polypeptide which has a compact tertiary or quaternary structure with a hydrophobic core. The invention provides for many different parent polypeptides to be used as the basis for the association domain. Suitable polypeptides can be identified by searching for compact, single-domain proteins or protein fragments in the database of known protein structures (Protein Data Bank, PDB) and selecting structures that are stable and can be expressed at high yields in recombinant form. These structures can then be analyzed for hydrophobic sub-clusters by the method of Karpeisky and Ilyn (1992, *J. Mol. Biol.* 224, 629-638) or for structural units (such as β -elements or helical hairpin structures) by standard molecular modelling techniques. In a further embodiment, the present invention

provides for multi-functional polypeptides wherein the single parent polypeptide is taken from the list ubiquitin, acyl phosphatase, IL-2, calbindin and myoglobin.

In a preferred embodiment, the present invention provides a multi-functional polypeptide comprising two or more amino acid sequences each attached to at least one functional domain, wherein any two or more of said amino acid sequences can associate in a complementary fashion to provide a parental, native like, tertiary or optionally quaternary structure.

Once structural sub-domains are identified, the protein is dissected in such a way these sub-domains remain intact. The selection process can be expanded to proteins for which no structure is available but which satisfy the criteria of stability and good expression. For these proteins, folding sub-domains can be determined by hydrogen exchange pulse-labelling of backbone amides during the folding reaction, followed by NMR detection in the native state (Roder et al., 1988, *Nature* 355, 700-704; Udgaonkar & Baldwin, 1988, *Science* 255, 594-597). Alternatively, folding sub-domains can be identified by mild proteolysis, denaturation, purification of fragments and reconstitution *in vitro* (Tasayco & Carey, 1992, *Science* 255, 594-597; Wu et al., 1993, *Biochemistry* 32, 10271-10276). Finally, additional clues for the choice of cleavage sites can be obtained from the exon structure in the case of eukaryotic proteins, since the exons frequently (though not always) correspond to structural sub-domains of a protein. This has, for example, been discussed for the case of myoglobin (Go 1981, *Nature* 291, 90).

The yield of properly assembled molecules is expected to decrease significantly for constructs in which a protein domain is divided into three or more parts. This is due to the fact that several sub-domains must come together simultaneously to form a viable structure. This effect is countered by dividing the polypeptide chain into sub-domains that represent folding units (identified by the methods described above). Thus, not only the final, assembled complex but also assembly intermediates will have the stability necessary to allow their accumulation in the

host during expression, resulting in a greatly improved kinetic behaviour of the system.

In solution, the isolated segments have little secondary structure and remain monomeric or form transient, non-specific and easily disrupted aggregates. Only upon mixing, either by separate expression and purification, or by co-expression, can the concerted folding of complementary segments provide the necessary intermediate interaction of residues (Matthews, 1993, *Annu. Rev. Biochem.* 62, 653 - 683) that results in the formation of a compact, native-like structure. This association, mainly driven by the burial of hydrophobic residues of all segments into a single hydrophobic core, leads to a targeted assembly of the N- or C-terminally fused proteins to a multi-functional complex *in vivo* or *in vitro*.

Optionally, the reconstituted native-like structure may also contribute an enzymatic or binding activity to increase the number of effector functions in the assembled complex. Accordingly, the present invention also provides a multi-functional polypeptide as described above, in which the native-like, tertiary or quaternary structure provides a biological activity. For example, when acyl phosphatase is used as the basis of the association domain, it is expected that the multi-functional polypeptide will retain some phosphatase activity.

The present invention provides for many different types of functional domains to be linked into the multi-functional polypeptide. Particularly preferred are cases in which one or more, preferably two, of said functional domains are fragments derived from molecules of the immunoglobulin superfamily. In particularly preferred embodiments, said fragments are antibody fragments. Also preferred are cases in which at least one of the functional domains possesses biological activity other than that associated with a fragment derived from a member of the immunoglobulin superfamily. By way of example, the present invention provides for the targeted assembly of enzymes, toxins, cytokines, peptide hormones, immunoglobulins, metal binding domains, soluble receptors, lectins, lipoproteins, purification tails and bioactive peptides to multi-functional complexes (Fig. 1) based on a modular system of expression vectors, restriction sites and "plug-in" gene cassettes coding for assembly segments, peptide linkers and functional domains (Fig.2).

If covalent linkage between the segments is necessary to prevent dissociation at low concentrations, cysteines can be introduced to form inter-segmental disulphide bridges between the amino acid sequences which comprise the association domain (Ecker et al., 1989, *J. Biol. Chem.* 264, 1887-1893; Pack & Plückthun, 1992, *Biochemistry* 31, 1579-1584). Accordingly, the present invention provides multi-functional polypeptides wherein the folding of the component amino acid sequences is stabilized by a covalent bond.

In order to provide some flexibility between the association domain and the appended functional domains, it may be desired to incorporate a linker peptide. Accordingly, the present invention provides for multi-functional polypeptides of the type described above wherein at least one of the functional domains is coupled to said amino acid sequence via a flexible peptide linker. By way of example, the flexible linker may be derived from the hinge region of an antibody. The invention enables even more complex multi-functional polypeptides to be constructed via the attachment of at least one further (poly)peptide to one or more of said amino acid sequences. By way of example, the further (poly)peptide can be taken from the list enzymes, toxins, cytokines, peptide hormones, immunoglobulins, metal binding domains, soluble receptors, lectins, lipoproteins, purification tails, in particular peptides which are able to bind to an independent binding entity, bioactive peptides, preferably of 5 to 15 amino acid residues, metal binding proteins, DNA binding domains, transcription factors and growth factors.

For therapeutic purposes, it is often desirable that proteinaceous substances display the minimum possible immunogenicity. Accordingly, the present invention provides for multi-functional polypeptides as described above in which at least one of said amino acid sequences, functional domains, or further (poly)peptides is of human origin.

In addition to the peptides and proteins provided above, the present invention also provides for DNA sequences, vectors, preferably bicistronic vectors, vector cassettes, characterised in that they comprise a DNA sequence encoding an amino acid sequence and optionally at least one further (poly)peptide comprised in the multifunctional polypeptide of the invention, and additionally at least one,

preferably singular cloning sites for inserting the DNA encoding at least one further functional domain or that they comprise DNA sequences encoding the amino acid sequences, and optionally the further (poly)peptide(s) comprised in the multifunctional polypeptide of the invention and suitable restriction sites for the cloning of DNA sequences encoding the functional domains, such that upon expression of the DNA sequences after the insertion of the DNA sequences encoding the functional domains into said restriction sites, in a suitable host the multifunctional polypeptide of the invention is formed. In a preferred embodiment said vector cassette is characterised in that it comprises the inserted DNA sequence(s) encoding said functional domain(s) and host cells transformed with at least one vector or vector cassette of the invention which can be used for the preparation of said multi-functional polypeptides.

In a further preferred embodiment, said host cell is a mammalian, preferably human, yeast, insect, plant or bacterial, preferably *E. coli* cell.

The invention further provides for a method for the production of a multifunctional polypeptide of the invention, which comprises culturing the host cell of the invention in a suitable medium, and recovering said multifunctional polypeptide produced by said host cell.

In a further embodiment, the invention relates to a method for the production of a multifunctional polypeptide of the invention which comprises culturing at least two host cells of the invention in a suitable medium, said host cells each producing only one of said first and said second amino acid sequences attached to at least one further functional domain, recovering the amino acid sequences, mixing thereof under mildly denaturing conditions and allowing in vitro folding of the multifunctional polypeptide of the invention from said amino acid sequences.

In a particular preferred embodiment, said method is characterised in that the further amino acid sequences attached to at least one further functional domain

are/is produced by at least one further host cell not producing said first or second amino acid sequence.

In another particularly preferred embodiment of the invention, said method is characterised in that at least one further amino acid sequence attached to at least one further functional domain is produced by the host cell of the invention producing said first or second amino acid sequence.

In further preferred embodiments, the present invention provides for pharmaceutical and diagnostic compositions comprising the multi-functional polypeptides described above, said pharmaceutical compositions optionally comprising a pharmaceutically acceptable carrier. Finally, the invention provides for a kit comprising one or more vector cassettes useful in the preparation of said multi-functional polypeptides.

The invention is now illustrated by reference to the following examples, which are provided for the purposes of illustration only and are not intended to limit the scope of the invention.

Example 1: Segmented human ubiquitin as an assembly device

Ubiquitin is a compact intracellular protein of only 76 residues (Fig. 3) and a molecular weight of 5 kDa. It shows the highest conservation among all known proteins and is involved in the degradation pathway of intracellular eukaryotic proteins by forming intermediate isopeptide bonds to its C-terminus and to Lys48 (Hershko & Ciechanover, 1992, *Ann. Rev. Biochem.* 61, 761-807).

To use ubiquitin as an assembly device, the unwanted function can be abolished by truncation of the last three C-terminal residues (--Arg-Gly-Gly), and the exchange of Lys48 to Arg, which prevents the formation of isopeptide bonds to this residue. The altered sequence is then divided in a loop at position Gly36, so that the hydrophobic core falls apart into two segments (called ALPHA and BETA). The synthetic nucleotide sequence of the segments (Fig 4, 5) carry appropriate restriction sites (MroI-HindIII) at the termini, so that the cassette encoding the segments can be easily ligated to a EcoRI-MroI cassette encoding the flexible linker (hinge of hulgG3; Fig. 6). The cassettes are inserted into the expression vector pIG3 (EcoRI-HindIII; Fig. 7) encoding the scFv fragment of the antibody McPC603 under the lac promoter/operator (Ge et al., 1995, in: *Antibody engineering: A practical approach*. IRL Press, New York, Borrebaeck ed., 229-261). Insertion of a second functional fragment (scFv fragment of the anti- β -lactam antibody 2H10 with phoA signal sequence) linked to association segment BETA as an XbaI-HindIII DNA fragment (Fig. 8) results in a di-cistronic expression vector (Pack, 1994, Ph. D. thesis, Ludwig-Maximilians-Universität München). After induction with IPTG and translation, the signal sequences guide the antibody fragments fused to the assembly segments to the periplasm, where they assemble to a complex with a reconstituted native-like ubiquitin fold and two different antibody specificities. The complex, a bispecific immunoglobulin, can be recovered and purified by affinity chromatography of cell extract (Pack, 1994, Ph. D. thesis, Ludwig-Maximilians-Universität München).

Example 2: Covalent linkage of the native-like tertiary structure of the assembly device by engineered disulphide bridges and combination of a C-terminal peptide linker with an in-frame restriction site.

The conformational stability of undivided, native ubiquitin can be enhanced by introduction of disulfides at positions 4 and 66 without perturbation in the backbone (Ecker et al., 1989, *J. Biol. Chem.* 264, 1887-1893; Fig. 9). In the context of this invention, the engineering of disulfide bridges provides the covalent linkage of segments (Fig. 10, 11) after co-folding and assembly.

To raise the number of possible functional domains in the assembled complex, a C-terminal peptide can be fused to one or more of the segments of the assembly device. To fuse a functional domain like an enzyme, cytokine, antibody fragment, purification peptide or toxin to this linker, a restriction site, preferably unique, has to be introduced in-frame (Fig. 11). Gene synthesis, cloning, expression as well as recovery of the assembled, covalently linked complex is according to example 1.

Example 3: Segmented human interleukin-2 (IL2) as an assembly device

Human interleukin-2 (Brandhuber et al., 1987, *Science* 238, 1707 - 1709; Kuziel & Greene, 1991, in: *The Cytokine Handbook*. Academic Press, 84-100) is used as an assembly device by segmentation between position His79 and Lys 80 (Fig. 12). The device, encoded by MroI-Ascl-HindII gene cassettes (Fig. 13, 14) combines the low immunogenicity of the plasmatic protein with a preferable effector function of the native-like cytokine structure and an inter-segmental cysteine bridge (Cys58-Cys105) after assembly. The combination of one or more antibody fragments against tumor antigens with additional cytokines like IL6 or

IL12 targets the multi-cytokine complex (Rock et al., 1992, *Prot. Eng.* 5, 583-591) directly to the tumour.

Example 4 : Segmented human apomyoglobin as an assembly device with three segments

To use more than two segments of a native structure as an assembly device, the hydrophobic interface between the segments has to be large enough to provide the sufficient hydrophobic interaction for non-covalent linkage. Myoglobin (Fig.15) is expressible in large amounts in *E. coli* (Guillemette et al., 1991, *Protein Eng.* 4, 585-592). Up to six functional domains can be assembled by a threefold segmented structure (Fig. 16, 17, 18), three at the N-termini and three at the C-termini of the segments. The presence of heme additionally stabilizes the native-like apomyoglobin fold and can be used as a switch to influence the association constant of the multi-functional complex.

Example 5: Bioactive peptides as functional domains

Certain peptides derived from amphipathic loop structures of LPS-binding proteins (Hoess et al., 1993, *EMBO J.* 12, 3351-3356) are able to neutralize endotoxin. This effect is enhanced by multivalent display of these short peptides (10-15 residues; Hoess, unpublished results). The present invention provides a method to express and assemble several of short peptides (Fig.19), fused to an assembly segment, in a multivalent complex or in combination with other functional domains. The peptides can be fused either to the N-or to the C-terminus (Fig. 20, 21) of the assembly domain via the peptide linkers.

Example 6: A purification tail for IMAC as a functional domain

Peptide tails consisting of histidines are able to coordinate metal ions. They are used for purification of native proteins in immobilized metal affinity chromatography (IMAC). Multivalent display of the purification tail considerably improves the maximum purity achievable by IMAC (Lindner et al., 1992, *Methods: a companion to methods in enzymology* 4, 41-56). One or more gene cassettes (Fig. 22) encoding a polyhistidine tail can be fused to the assembly segment to provide a simple and efficient purification method for multi-functional complexes.

Example 7: The platelet aggregation inhibitor decorsin as a functional domain

Decorsin, a 39 residue protein of the leech *Macrobdella decora* (Fig. 23), acts as a potent antagonist of the platelet glycoprotein IIb-IIIa (Seymour et al., 1990, *J. Biol. Chem.* 265, 10143-10147). The gene cassette encoding the decorsin can be fused C- or N-terminally to an association segment (Fig. 24, 25). In arterial thrombotic diseases, a multivalent decorsin complex combined with an anti-fibrin antibody fragment can act as a powerful antithrombotic agent.

Claims

1. A multifunctional polypeptide comprising:
 - (a) a first amino acid sequence attached to at least one functional domain;
 - (b) a second amino acid sequence attached to at least one further functional domain; and
 - (c) optionally, further amino acid sequences each attached to at least one further functional domain;wherein any one or more of said amino acid sequences interacts with at least one of said amino acid sequences in a complementary fashion to form a parental, native-like tertiary or optionally quaternary structure and wherein said parental, native-like tertiary or optionally quaternary structure is derived from a single parent polypeptide.
2. The multifunctional polypeptide according to claim 1, wherein said single parent polypeptide is ubiquitin, acyl-phosphatase, IL2, calbindin or apomyoglobin.
3. The multifunctional polypeptide according to claim 1 or 2, wherein said parental, native-like tertiary or optionally quaternary structure is biologically active.
4. The multifunctional polypeptide according to any one of claims 1 to 3, wherein at least one of said functional domains is a fragment derived from a member of the immunoglobulin superfamily.
5. The multifunctional polypeptide according to claim 4, wherein two of said functional domains are fragments derived from members of the immunoglobulin superfamily.

6. The multifunctional polypeptide according to claim 4 or 5, wherein said fragments are antibody fragments.
7. The multifunctional polypeptide according to any one of claims 1 to 6, wherein at least one of said functional domains is a biologically active molecule or a derivative thereof other than a fragment derived from a member of the immunoglobulin superfamily.
8. The multifunctional polypeptide according to any one of claims 1 to 6, wherein the folding of the amino acid sequences is stabilised by a covalent bonding.
9. The multifunctional polypeptide according to any one of claims 1 to 8, wherein at least one of said functional domains is coupled to said amino acid sequence(s) via a flexible peptide linker.
10. The multifunctional polypeptide according to claim 9, wherein said flexible peptide linker is an antibody hinge region.
11. The multifunctional polypeptide according to any one of calims 1 to 10, wherein at least one of said amino acid sequences is coupled to at least one further (poly)peptide.
12. The multifunctional polypeptide according to claim 11, wherein said further (poly)peptide is an enzyme, a toxin, a cytokine, a metal binding site, a metal binding protein, a soluble receptor, a DNA-binding domain, a transcription factor, an immunoglobulin, a bioactive peptide of 5 to 15 amino acid residues, a peptide hormone, a growth factor, a lectin, a lipoprotein, and a peptide which is able to bind to an independent binding entity.

13. The multifunctional polypeptide according to any one of claims 1 to 12, wherein at least one of said amino acid sequences, functional domains or further (poly)peptide(s) is of human origin.
14. A DNA sequence encoding an amino acid sequence and at least one functional domain and, optionally, at least one further functional (poly)peptide comprised in the multifunctional polypeptide of any one of claims 1 to 13.
15. A vector comprising at least one DNA molecule of claim 14.
16. The vector of claim 15, which is a bicistronic vector.
17. A vector cassette characterised in that it comprises a DNA sequence encoding an amino acid sequence and optionally at least one further (poly)peptide comprised in the multifunctional polypeptide of any one of claims 1 to 13, and additionally at least one, preferably a singular cloning site for inserting the DNA encoding at least one further functional domain.
18. A vector cassette characterised in that it comprises DNA sequences encoding the amino acid sequences, and optionally the further (poly)peptide(s) comprised in the multifunctional polypeptide of any one of claims 1 to 13, and suitable restriction sites for the cloning of DNA sequences encoding the functional domains, such that upon expression of the DNA sequences after the insertion of the DNA sequences encoding the functional domains into said restriction sites, in a suitable host the multifunctional polypeptide according to any one of claims 1 to 13 is formed.

19. The vector cassette according to claim 17 or 18 characterised in that it comprises the inserted DNA sequence(s) encoding said functional domain(s).
20. A host cell transformed with at least one vector according to claim 15 or 16, or at least one vector cassette according to claim 19.
21. The host cell according to claim 20, which is a mammalian, preferably human, yeast, insect, plant or bacterial, preferably E. coli cell.
22. A method for the production of a multifunctional polypeptide according to any one of claims 1 to 13, which comprises culturing the host cell according to claim 20 or 21 in a suitable medium, and recovering said multifunctional polypeptide produced by said host cell.
23. A method for the production of a multifunctional polypeptide according to any one of claims 1 to 13 which comprises culturing at least two host cells according to claim 20 or 21 in a suitable medium, said host cells each producing only one of said first and said second amino acid sequences attached to at least one further functional domain, recovering the amino acid sequences, mixing thereof under mildly denaturing conditions and allowing in vitro folding of the multifunctional polypeptide according to any one of claims 1 to 13 from said amino acid sequences.
24. The method according to claim 23, wherein the further amino acid sequence(s) (each) attached to at least one further functional domain are/is produced by at least one further host cell not producing said first or second amino acid sequence.

25. The method according to claim 23, wherein at least one further amino acid sequence attached to at least one further functional domain is produced by the host cell according to claim 20 or 21 producing said first or second amino acid sequence.
26. A pharmaceutical composition comprising the multifunctional polypeptide according to any one of claims 1 to 13 optionally in combination with a pharmaceutically acceptable carrier.
27. A diagnostic composition comprising the multifunctional polypeptide according to any one of claims 1 to 13.
28. A kit comprising at least one vector cassette according to claim 17 or 18.

(54) Title: MODULATORS OF AMYLOID AGGREGATION (57) Abstract <p>Compounds that modulate the aggregation of amyloidogenic proteins or peptides are disclosed. The modulators of the invention can promote amyloid aggregation or, more preferably, can inhibit natural amyloid aggregation. In a preferred embodiment, the compounds modulate the aggregation of natural β amyloid peptides (β-AP). In a preferred embodiment, the β amyloid modulator compounds of the invention are comprised of an Aβ aggregation core domain and a modifying group coupled thereto such that the compound alters the aggregation or inhibits the neurotoxicity of natural β amyloid peptides when contacted with the peptides. Furthermore, the modulators are capable of altering natural β-AP aggregation when the natural β-APs are in a molar excess amount relative to the modulators. Pharmaceutical compositions comprising the compounds of the invention, and diagnostic and treatment methods for amyloidogenic diseases using the compounds of the invention, are also disclosed.</p>

MODULATORS OF AMYLOID AGGREGATION

Background of the Invention

Alzheimer's disease (AD), first described by the Bavarian psychiatrist Alois
5 Alzheimer in 1907, is a progressive neurological disorder that begins with short term memory
loss and proceeds to disorientation, impairment of judgement and reasoning and, ultimately,
dementia. The course of the disease usually leads to death in a severely debilitated, immobile
state between four and 12 years after onset. AD has been estimated to afflict 5 to 11 percent
of the population over age 65 and as much as 47 percent of the population over age 85. The
10 societal cost for managing AD is upwards of 80 billion dollars annually, primarily due to the
extensive custodial care required for AD patients. Moreover, as adults born during the
population boom of the 1940's and 1950's approach the age when AD becomes more
prevalent, the control and treatment of AD will become an even more significant health care
problem. Currently, there is no treatment that significantly retards the progression of the
15 disease. For reviews on AD, see Selkoe, D.J. *Sci. Amer.*, November 1991, pp. 68-78; and
Yankner, B.A. *et al.* (1991) *N. Eng. J. Med.* 325:1849-1857.

It has recently been reported (Games *et al.* (1995) *Nature* 373:523-527) that an
Alzheimer-type neuropathology has been created in transgenic mice. The transgenic mice
express high levels of human mutant amyloid precursor protein and progressively develop
20 many of the pathological conditions associated with AD.

Pathologically, AD is characterized by the presence of distinctive lesions in the
victim's brain. These brain lesions include abnormal intracellular filaments called
neurofibrillary tangles (NTFs) and extracellular deposits of amyloidogenic proteins in senile,
or amyloid, plaques. Amyloid deposits are also present in the walls of cerebral blood vessels
25 of AD patients. The major protein constituent of amyloid plaques has been identified as a 4
kilodalton peptide called β -amyloid peptide (β -AP) (Glenner, G.G. and Wong, C.W. (1984)
Biochem. Biophys. Res. Commun. 120:885-890; Masters, C. *et al.* (1985) *Proc. Natl. Acad.
Sci. USA* 82:4245-4249). Diffuse deposits of β -AP are frequently observed in normal adult
brains, whereas AD brain tissue is characterized by more compacted, dense-core β -amyloid
30 plaques. (See *e.g.*, Davies, L. *et al.* (1988) *Neurology* 38:1688-1693) These observations
suggest that β -AP deposition precedes, and contributes to, the destruction of neurons that
occurs in AD. In further support of a direct pathogenic role for β -AP, β -amyloid has been
shown to be toxic to mature neurons, both in culture and *in vivo*. Yankner, B.A. *et al.* (1989)
Science 245:417-420; Yankner, B.A. *et al.* (1990) *Proc. Natl. Acad. Sci. USA* 87:9020-9023;
35 Roher, A.E. *et al.* (1991) *Biochem. Biophys. Res. Commun.* 174:572-579; Kowall, N.W. *et al.*
(1991) *Proc. Natl. Acad. Sci. USA* 88:7247-7251. Furthermore, patients with hereditary
cerebral hemorrhage with amyloidosis-Dutch-type (HCHWA-D), which is characterized by
diffuse β -amyloid deposits within the cerebral cortex and cerebrovasculature, have been
shown to have a point mutation that leads to an amino acid substitution within β -AP. Levy,

E. *et al.* (1990) *Science* 248:1124-1126. This observation demonstrates that a specific alteration of the β -AP sequence can cause β -amyloid to be deposited.

Natural β -AP is derived by proteolysis from a much larger protein called the amyloid precursor protein (APP). Kang, J. *et al.* (1987) *Nature* 325:733; Goldgaber, D. *et al.* (1987) *Science* 235:877; Robakis, N.K. *et al.* (1987) *Proc. Natl. Acad. Sci. USA* 84:4190; Tanzi, R.E. *et al.* (1987) *Science* 235:880. The APP gene maps to chromosome 21, thereby providing an explanation for the β -amyloid deposition seen at an early age in individuals with Down's syndrome, which is caused by trisomy of chromosome 21. Mann, D.M. *et al.* (1989) *Neuropathol. Appl. Neurobiol.* 15:317; Rumble, B. *et al.* (1989) *N. Eng. J. Med.* 320:1446.

APP contains a single membrane spanning domain, with a long amino terminal region (about two-thirds of the protein) extending into the extracellular environment and a shorter carboxy-terminal region projecting into the cytoplasm. Differential splicing of the APP messenger RNA leads to at least five forms of APP, composed of either 563 amino acids (APP-563), 695 amino acids (APP-695), 714 amino acids (APP-714), 751 amino acids (APP-751) or 770 amino acids (APP-770).

Within APP, naturally-occurring β amyloid peptide begins at an aspartic acid residue at amino acid position 672 of APP-770. Naturally-occurring β -AP derived from proteolysis of APP is 39 to 43 amino acid residues in length, depending on the carboxy-terminal end point, which exhibits heterogeneity. The predominant circulating form of β -AP in the blood and cerebrospinal fluid of both AD patients and normal adults is β 1-40 ("short β "). Seubert, P. *et al.* (1992) *Nature* 359:325; Shoji, M. *et al.* (1992) *Science* 258:126. However, β 1-42 and β 1-43 ("long β ") also are forms in β -amyloid plaques. Masters, C. *et al.* (1985) *Proc. Natl. Acad. Sci. USA* 82:4245; Miller, D. *et al.* (1993) *Arch. Biochem. Biophys.* 301:41; Mori, H. *et al.* (1992) *J. Biol. Chem.* 267:17082. Although the precise molecular mechanism leading to β -APP aggregation and deposition is unknown, the process has been likened to that of nucleation-dependent polymerizations, such as protein crystallization, microtubule formation and actin polymerization. See *e.g.*, Jarrett, J.T. and Lansbury, P.T. (1993) *Cell* 73:1055-1058. In such processes, polymerization of monomer components does not occur until nucleus formation. Thus, these processes are characterized by a lag time before aggregation occurs, followed by rapid polymerization after nucleation. Nucleation can be accelerated by the addition of a "seed" or preformed nucleus, which results in rapid polymerization. The long β forms of β -AP have been shown to act as seeds, thereby accelerating polymerization of both long and short β -AP forms. Jarrett, J.T. *et al.* (1993) *Biochemistry* 32:4693.

In one study, in which amino acid substitutions were made in β -AP, two mutant β peptides were reported to interfere with polymerization of non-mutated β -AP when the mutant and non-mutant forms of peptide were mixed. Hilbich, C. *et al.* (1992) *J. Mol. Biol.* 228:460-473. However, equimolar amounts of the mutant and non-mutant (*i.e.*, natural) β

amyloid peptides were used to see this effect³ and the mutant peptides were reported to be unsuitable for use *in vivo*. Hilbich, C. *et al.* (1992), *supra*.

Summary of the Invention

This invention pertains to compounds, and pharmaceutical compositions thereof, that can modulate the aggregation of amyloidogenic proteins and peptides, in particular compounds that can modulate the aggregation of natural β amyloid peptides (β -AP) and inhibit the neurotoxicity of natural β -APs. In one embodiment, the invention provides an amyloid modulator compound comprising an amyloidogenic protein, or peptide fragment thereof, coupled directly or indirectly to at least one modifying group such that the compound modulates the aggregation of natural amyloid proteins or peptides when contacted with the natural amyloidogenic proteins or peptides. Preferably, the compound inhibits aggregation of natural amyloidogenic proteins or peptides when contacted with the natural amyloidogenic proteins or peptides. The amyloidogenic protein, or peptide fragment thereof, can be, for example, selected from the group consisting of transthyretin (TTR), prion protein (PrP), islet amyloid polypeptide (IAPP), atrial natriuretic factor (ANF), kappa light chain, lambda light chain, amyloid A, procalcitonin, cystatin C, β 2 microglobulin, ApoA-I, gelsolin, procalcitonin, calcitonin, fibrinogen and lysozyme.

In the most preferred embodiment of the invention, the compound modulates the aggregation of natural β -AP. The invention provides a β -amyloid peptide compound comprising a formula:

wherein Xaa is a β -amyloid peptide having an amino-terminal amino acid residue corresponding to position 668 of β -amyloid precursor protein-770 (APP-770) or to a residue carboxy-terminal to position 668 of APP-770, A is a modifying group attached directly or indirectly to the β -amyloid peptide of the compound such that the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides, and n is an integer selected such that the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

In one embodiment, at least one A group is attached directly or indirectly to the amino terminus of the β -amyloid peptide of the compound. In another embodiment, at least one A group is attached directly or indirectly to the carboxy terminus of the β -amyloid peptide of the compound. In yet another embodiment, at least one A group is attached directly or indirectly to a side chain of at least one amino acid residue of the β -amyloid peptide of the compound.

The invention also provides a β -amyloid modulator compound comprising an A β aggregation core domain (ACD) coupled directly or indirectly to at least one modifying group (MG) such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

- 5 Preferably, the A β aggregation core domain is modeled after a subregion of natural β -amyloid peptide between 3 and 10 amino acids in length.

The invention also provides β -amyloid modulator compound comprising a formula:

10

wherein Xaa₁, Xaa₂ and Xaa₃ are each amino acid structures and at least two of Xaa₁, Xaa₂ and Xaa₃ are, independently, selected from the group consisting of a leucine structure, a phenylalanine structure and a valine structure;

- 15 Y, which may or may not be present, is a peptidic structure having the formula (Xaa)_a, wherein Xaa is any amino acid structure and a is an integer from 1 to 15;

Z, which may or may not be present, is a peptidic structure having the formula (Xaa)_b, wherein Xaa is any amino acid structure and b is an integer from 1 to 15; and

A is a modifying group attached directly or indirectly to the compound and n is an integer;

- 20 Xaa₁, Xaa₂, Xaa₃, Y, Z, A and n being selected such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. In a preferred embodiment, Xaa₁ and Xaa₂ are each phenylalanine structures. In another preferred embodiment Xaa₂ and Xaa₃ are each phenylalanine structures.

- 25 The invention further provides a β -amyloid modulator compound comprising a formula:

- 30 wherein Xaa₁ and Xaa₃ are amino acid structures;

Xaa₂ is a valine structure;

Xaa₄ is a phenylalanine structure;

Y, which may or may not be present, is a peptidic structure having the formula (Xaa)_a, wherein Xaa is any amino acid structure and a is an integer from 1 to 15;

- 35 Z, which may or may not be present, is a peptidic structure having the formula (Xaa)_b, wherein Xaa is any amino acid structure and b is an integer from 1 to 15; and

5

A is a modifying group attached directly or indirectly to the compound and n is an integer;

Xaa₁, Xaa₃, Y, Z, A and n being selected such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. In a preferred embodiment, Xaa₁ is a leucine structure and Xaa₃ is phenylalanine structure.

The invention still further provides a compound comprising the formula:

wherein Xaa₁ is a histidine structure;

Xaa₂ is a glutamine structure;

Xaa₃ is a lysine structure;

Xaa₄ is a leucine structure;

Xaa₅ is a valine structure;

Xaa₆ is a phenylalanine structure;

Xaa₇ is a phenylalanine structure;

Xaa₈ is an alanine structure;

A and B are modifying groups attached directly or indirectly to the amino terminus and carboxy terminus, respectively, of the compound;

and wherein Xaa₁-Xaa₂-Xaa₃, Xaa₁-Xaa₂ or Xaa₁ may or may not be present;

Xaa₈ may or may not be present; and

at least one of A and B is present.

The invention still further provides a β -amyloid modulator compound comprising a modifying group attached directly or indirectly to a peptidic structure, wherein the peptidic structure comprises amino acid structures having an amino acid sequence selected from the group consisting of His-Gln-Lys-Leu-Val-Phe-Phe-Ala (SEQ ID NO: 5), His-Gln-Lys-Leu-Val-Phe-Phe (SEQ ID NO: 6), Gln-Lys-Leu-Val-Phe-Phe-Ala (SEQ ID NO: 7), Gln-Lys-Leu-Val-Phe-Phe (SEQ ID NO: 8), Lys-Leu-Val-Phe-Phe-Ala (SEQ ID NO: 9), Lys-Leu-Val-Phe-Phe (SEQ ID NO: 10), Leu-Val-Phe-Phe-Ala (SEQ ID NO: 11), Leu-Val-Phe-Phe (SEQ ID NO: 12), Leu-Ala-Phe-Phe-Ala (SEQ ID NO: 13), Val-Phe-Phe (SEQ ID NO: 19), Phe-Phe-Ala (SEQ ID NO: 20), Phe-Phe-Val-Leu-Ala (SEQ ID NO: 21), Leu-Val-Phe-Phe-Lys (SEQ ID NO: 22), Leu-Val-Iodotyrosine-Phe-Ala (SEQ ID NO: 23), Val-Phe-Phe-Ala (SEQ ID NO: 24), Ala-Val-Phe-Phe-Ala (SEQ ID NO: 25), Leu-Val-Phe-Iodotyrosine-Ala (SEQ ID NO: 26), Leu-Val-Phe-Phe-Ala-Glu (SEQ ID NO: 27), Phe-Phe-Val-Leu (SEQ ID NO: 28), Phe-Lys-Phe-Val-Leu (SEQ ID NO: 29), Lys-Leu-Val-Ala-Phe (SEQ ID NO: 30), Lys-Leu-Val-Phe-Phe- β Ala (SEQ ID NO: 31) and Leu-Val-Phe-Phe-DAla (SEQ ID NO: 32).

In the compounds of the invention comprising a modifying group, preferably the modifying group comprises a cyclic, heterocyclic or polycyclic group. Preferred modifying

6
groups contains a cis-decalin group, such as a cholanoyl structure. Preferred modifying groups include a cholyl group, a biotin-containing group, a diethylene-triaminepentaacetyl group, a (-)-menthoxyacetyl group, a fluorescein-containing group or an N-acetylneuraminy group.

5 The compounds of the invention can be further modified, for example to alter a pharmacokinetic property of the compound or to label the compound with a detectable substance. Preferred radioactive labels are radioactive iodine or technetium.

The invention also provides a β -amyloid modulator which inhibits aggregation of natural β -amyloid peptides when contacted with a molar excess amount of natural β -amyloid
10 peptides.

The invention also provides a β -amyloid peptide compound comprising an amino acid sequence having at least one amino acid deletion compared to β AP₁₋₃₉, such that the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. In one embodiment, the compound has at least one internal amino acid
15 deleted compared to β AP₁₋₃₉. In another embodiment, the compound has at least one N-terminal amino acid deleted compared to β AP₁₋₃₉. In yet another embodiment, the compound has at least one C-terminal amino acid deleted compared to β AP₁₋₃₉. Preferred compounds include β AP₆₋₂₀ (SEQ ID NO: 13), β AP₁₆₋₃₀ (SEQ ID NO: 14), β AP_{1-20, 26-40} (SEQ ID NO: 15) and EEVVHHHHQQ- β AP₁₆₋₄₀ (SEQ ID NO: 16).

20 The compounds of the invention can be formulated into pharmaceutical compositions comprising the compound and a pharmaceutically acceptable carrier. The compounds can also be used in the manufacture of a medicament for the diagnosis or treatment of an amyloidogenic disease.

Another aspect of the invention pertains to diagnostic and treatment methods using
25 the compounds of the invention. The invention provides a method for inhibiting aggregation of natural β -amyloid peptides, comprising contacting the natural β -amyloid peptides with a compound of the invention such that aggregation of the natural β -amyloid peptides is inhibited. The invention also provides a method for inhibiting neurotoxicity of natural β -amyloid peptides, comprising contacting the natural β -amyloid peptides with a compound of
30 the invention such that neurotoxicity of the natural β -amyloid peptides is inhibited.

In another embodiment, the invention provides a method for detecting the presence or absence of natural β -amyloid peptides in a biological sample, comprising contacting a biological sample with a compound of the invention and detecting the compound bound to natural β -amyloid peptides to thereby detect the presence or absence of natural β -amyloid
35 peptides in the biological sample. In one embodiment, the β -amyloid modulator compound and the biological sample are contacted *in vitro*. In another embodiment, the β -amyloid modulator compound is contacted with the biological sample by administering the β -amyloid modulator compound to a subject. For *in vivo* administration, preferably the compound is labeled with radioactive technetium or radioactive iodine.

7
In another embodiment, the invention provides a method for detecting natural β -amyloid peptides to facilitate diagnosis of a β -amyloidogenic disease, comprising contacting a biological sample with a compound of the invention and detecting the compound bound to natural β -amyloid peptides to facilitate diagnosis of a β -amyloidogenic disease. In one
5 embodiment, the β -amyloid modulator compound and the biological sample are contacted *in vitro*. In another embodiment, the β -amyloid modulator compound is contacted with the biological sample by administering the β -amyloid modulator compound to a subject. For *in vivo* administration, preferably the compound is labeled with radioactive technetium or radioactive iodine. Preferably, the method facilitates diagnosis of Alzheimer's disease.

10 The invention also provides a method for treating a subject for a disorder associated with amyloidosis, comprising administering to the subject a therapeutically or prophylactically effective amount of a compound of the invention such that the subject is treated for a disorder associated with amyloidosis. The method can be used to treat disorders is selected, for example, from the group consisting of familial amyloid polyneuropathy
15 (Portuguese, Japanese and Swedish types), familial amyloid cardiomyopathy (Danish type), isolated cardiac amyloid, systemic senile amyloidosis, scrapie, bovine spongiform encephalopathy, Creutzfeldt-Jakob disease, Gerstmann-Straussler-Scheinker syndrome, adult onset diabetes, insulinoma, isolated atrial amyloidosis, idiopathic (primary) amyloidosis, myeloma or macroglobulinemia-associated amyloidosis, primary localized cutaneous
20 nodular amyloidosis associated with Sjogren's syndrome, reactive (secondary) amyloidosis, familial Mediterranean Fever and familial amyloid nephropathy with urticaria and deafness (Muckle-Wells syndrome), hereditary cerebral hemorrhage with amyloidosis of Icelandic type, amyloidosis associated with long term hemodialysis, hereditary non-neuropathic systemic amyloidosis (familial amyloid polyneuropathy III), familial amyloidosis of Finnish
25 type, amyloidosis associated with medullary carcinoma of the thyroid, fibrinogen-associated hereditary renal amyloidosis and lysozyme-associated hereditary systemic amyloidosis.

In a preferred embodiment, the invention provides a method for treating a subject for a disorder associated with β -amyloidosis, comprising administering to the subject a
30 therapeutically or prophylactically effective amount of a compound of the invention such that the subject is treated for a disorder associated with β -amyloidosis. Preferably the disorder is Alzheimer's disease.

In yet another embodiment, the invention provides a method for treating a subject for a disorder associated with β -amyloidosis, comprising administering to the subject a
35 recombinant expression vector encoding a peptide compound of the invention such that the compound is synthesized in the subject and the subject is treated for a disorder associated with β -amyloidosis. Preferably, the disorder is Alzheimer's disease.

Brief Description of the Drawing

4

Figure 1 is a graphic representation of the turbidity of a β -AP₁₋₄₀ solution, as measured by optical density at 400 nm, either in the absence of a β -amyloid modulator or in the presence of the β -amyloid modulator N-biotinyl- β AP₁₋₄₀ (1 %, or 5%).

Figure 2 is a schematic representation of compounds which can be used to modify a β -AP or an A β aggregation core domain to form a β -amyloid modulator of the invention.

Figure 3 is a graphic representation of the toxicity of A β ₁₋₄₀ aggregates, but not A β ₁₋₄₀ monomers, to cultured neuronal cells.

Figure 4 is a graphic representation of the aggregation of A β ₁₋₄₀ in the presence of an equimolar amount of choly-A β ₆₋₂₀ (panel A), a ~2-fold molar excess of choly-A β ₆₋₂₀ (panel B) or a ~6-fold molar excess of choly-A β ₆₋₂₀ (panel C) and the corresponding toxicity of the aggregates of panels A, B and C to cultured neuronal cells (panels D, E and F, respectively).

Detailed Description of the Invention

This invention pertains to compounds, and pharmaceutical compositions thereof, that can modulate the aggregation of amyloidogenic proteins and peptides, in particular compounds that can modulate the aggregation of natural β amyloid peptides (β -AP) and inhibit the neurotoxicity of natural β -APs. A compound of the invention that modulates aggregation of natural β -AP, referred to herein interchangeably as a β amyloid modulator compound, a β amyloid modulator or simply a modulator, alters the aggregation of natural β -AP when the modulator is contacted with natural β -AP. Thus, a compound of the invention acts to alter the natural aggregation process or rate for β -AP, thereby disrupting this process. Preferably, the compounds inhibit β -AP aggregation. Furthermore, the invention provides subregions of the β amyloid peptide that are sufficient, when appropriately modified as described herein, to alter (and preferably inhibit) aggregation of natural β amyloid peptides when contacted with the natural β amyloid peptides. In particular, preferred modulator compounds of the invention are comprised of a modified form of an A β aggregation core domain, modeled after the aforementioned A β subregion (as described further below), which is sufficient to alter (and preferably inhibit) the natural aggregation process or rate for β -AP. This A β aggregation core domain can comprises as few as three amino acid residues (or derivative, analogues or mimetics thereof). Moreover, while the amino acid sequence of the A β aggregation core domain can directly correspond to an amino acid sequence found in natural β -AP, it is not essential that the amino acid sequence directly correspond to a β -AP sequence. Rather, amino acid residues derived from a preferred subregion of β -AP (a hydrophobic region centered around positions 17-20) can be rearranged in order and/or substituted with homologous residues within a modulator compound of the invention and yet maintain their inhibitory activity (described further below).

a

The β amyloid modulator compounds of the invention can be selected based upon their ability to inhibit the aggregation of natural β -AP *in vitro* and/or inhibit the neurotoxicity of natural β -AP fibrils for cultured cells (using assays described herein). Accordingly, the preferred modulator compounds inhibit the aggregation of natural β -AP and/or inhibit the neurotoxicity of natural β -AP. However, modulator compounds selected based on one or both of these properties may have additional properties *in vivo* that may be beneficial in the treatment of amyloidosis. For example, the modulator compound may interfere with processing of natural β -AP (either by direct or indirect protease inhibition) or by modulation of processes that produce toxic β -AP, or other APP fragments, *in vivo*. Alternatively, modulator compounds may be selected based on these latter properties, rather than inhibition of A β aggregation *in vitro*. Moreover, modulator compounds of the invention that are selected based upon their interaction with natural β -AP also may interact with APP or with other APP fragments.

As used herein, a "modulator" of β -amyloid aggregation is intended to refer to an agent that, when contacted with natural β amyloid peptides, alters the aggregation of the natural β amyloid peptides. The term "aggregation of β amyloid peptides" refers to a process whereby the peptides associate with each other to form a multimeric, largely insoluble complex. The term "aggregation" further is intended to encompass β amyloid fibril formation and also encompasses β -amyloid plaques.

The terms "natural β -amyloid peptide", "natural β -AP" and "natural A β peptide", used interchangeably herein, are intended to encompass naturally occurring proteolytic cleavage products of the β amyloid precursor protein (APP) which are involved in β -AP aggregation and β -amyloidosis. These natural peptides include β -amyloid peptides having 39-43 amino acids (*i.e.*, A β ₁₋₃₉, A β ₁₋₄₀, A β ₁₋₄₁, A β ₁₋₄₂ and A β ₁₋₄₃). The amino-terminal amino acid residue of natural β -AP corresponds to the aspartic acid residue at position 672 of the 770 amino acid residue form of the amyloid precursor protein ("APP-770"). The 43 amino acid long form of natural β -AP has the amino acid sequence

DAEFRHDSGYEVHHQKLVFFAEDVGSNKGAIIGLMVGGVVIAT

(also shown in SEQ ID NO: 1), whereas the shorter forms have 1-4 amino acid residues deleted from the carboxy-terminal end. The amino acid sequence of APP-770 from position 672 (*i.e.*, the amino-terminus of natural β -AP) to its C-terminal end (103 amino acids) is shown in SEQ ID NO: 2. The preferred form of natural β -AP for use in the aggregation assays described herein is A β ₁₋₄₀.

In the presence of a modulator of the invention, aggregation of natural β amyloid peptides is "altered" or "modulated". The various forms of the term "alteration" or "modulation" are intended to encompass both inhibition of β -AP aggregation and promotion of β -AP aggregation. Aggregation of natural β -AP is "inhibited" in the presence of the modulator when there is a decrease in the amount and/or rate of β -AP aggregation as compared to the amount and/or rate of β -AP aggregation in the absence of the modulator.

The various forms of the term "inhibition" are intended to include both complete and partial inhibition of β -AP aggregation. Inhibition of aggregation can be quantitated as the fold increase in the lag time for aggregation or as the decrease in the overall plateau level of aggregation (*i.e.*, total amount of aggregation), using an aggregation assay as described in the Examples. In various embodiments, a modulator of the invention increases the lag time of aggregation at least 1.2-fold, 1.5-fold, 1.8-fold, 2-fold, 2.5-fold, 3-fold, 4-fold or 5-fold. In various other embodiments, a modulator of the invention inhibits the plateau level of aggregation at least 10%, 20%, 30%, 40 %, 50 %, 75 % or 100 %.

A modulator which inhibits β -AP aggregation (an "inhibitory modulator compound") can be used to prevent or delay the onset of β -amyloid deposition. Moreover, as demonstrated in Example 10, inhibitory modulator compounds of the invention inhibit the formation and/or activity of neurotoxic aggregates of natural A β peptide (*i.e.*, the inhibitory compounds can be used to inhibit the neurotoxicity of β -AP). Still further, also as demonstrated in Example 10, the inhibitory compounds of the invention can be used to reduce the neurotoxicity of preformed β -AP aggregates, indicating that the inhibitory modulators can either bind to preformed A β fibrils or soluble aggregate and modulate their inherent neurotoxicity or that the modulators can perturb the equilibrium between monomeric and aggregated forms of β -AP in favor of the non-neurotoxic form.

Alternatively, in another embodiment, a modulator compound of the invention promotes the aggregation of natural A β peptides. The various forms of the term "promotion" refer to an increase in the amount and/or rate of β -AP aggregation in the presence of the modulator, as compared to the amount and/or rate of β -AP aggregation in the absence of the modulator. Such a compound which promotes A β aggregation is referred to as a stimulatory modulator compound. Stimulatory modulator compounds may be useful for sequestering β -amyloid peptides, for example in a biological compartment where aggregation of β -AP may not be deleterious to thereby deplete β -AP from a biological compartment where aggregation of β -AP is deleterious. Moreover, stimulatory modulator compounds can be used to promote A β aggregation in *in vitro* aggregation assays (*e.g.*, assays such as those described in the Examples), for example in screening assays for test compounds that can then inhibit or reverse this A β aggregation (*i.e.*, a stimulatory modulator compound can act as a "seed" to promote the formation of A β aggregates).

In a preferred embodiment, the modulators of the invention are capable of altering β -AP aggregation when contacted with a molar excess amount of natural β -AP. A "molar excess amount of natural β -AP" refers to a concentration of natural β -AP, in moles, that is greater than the concentration, in moles, of the modulator. For example, if the modulator and β -AP are both present at a concentration of 1 μ M, they are said to be "equimolar", whereas if the modulator is present at a concentration of 1 μ M and the β -AP is present at a concentration of 5 μ M, the β -AP is said to be present at a 5-fold molar excess amount compared to the modulator. In preferred embodiments, a modulator of the invention is effective at altering

11
 natural β -AP aggregation when the natural β -AP is present at at least a 2-fold, 3-fold or 5-fold molar excess compared to the concentration of the modulator. In other embodiments, the modulator is effective at altering β -AP aggregation when the natural β -AP is present at at least a 10-fold, 20-fold, 33-fold, 50-fold, 100-fold, 500-fold or 1000-fold molar excess compared to the concentration of the modulator.

Various additional aspects of the modulators of the invention, and the uses thereof, are described in further detail in the following subsections.

I. Modulator Compounds

In one embodiment, a modulator of the invention comprises a β -amyloid peptide compound comprising the formula:

wherein Xaa is a β -amyloid peptide. A is a modulating group attached directly or indirectly to the β -amyloid peptide of the compound such that the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides, and n is an integer selected such that the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

Preferably, β -amyloid peptide of the compound has an amino-terminal amino acid residue corresponding to position 668 of β -amyloid precursor protein-770 (APP-770) or to a residue carboxy-terminal to position 668 of APP-770. The amino acid sequence of APP-770 from position 668 to position 770 (*i.e.*, the carboxy terminus) is shown below and in SEQ ID NO: 2:

EVKMDAEFRHDSGYEVHHQKLVFFAEDVGSNKGAIIGLMVGGVVIA TVIVITL
 VMLKKKQYTSIHG VVEVDAAVTPEERHLSKMQQNGYENPTYKFFEQMQN

More preferably, the amino-terminal amino acid residue of the β -amyloid peptide corresponds to position 672 of APP-770 (position 5 of the amino acid sequence of SEQ ID NO: 2) or to a residue carboxy-terminal to position 672 of APP-770. Although the β -amyloid peptide of the compound may encompass the 103 amino acid residues corresponding to positions 668-770 of APP-770, preferably the peptide is between 6 and 60 amino acids in length, more preferably between 10 and 43 amino acids in length and even more preferably between 10 and 25 amino acid residues in length.

As used herein, the term " β amyloid peptide", as used in a modulator of the invention is intended to encompass peptides having an amino acid sequence identical to that of the natural sequence in APP, as well as peptides having acceptable amino acid substitutions from the natural sequence. Acceptable amino acid substitutions are those that do not affect the

ability of the peptide to alter natural β -AP aggregation. Moreover, particular amino acid substitutions may further contribute to the ability of the peptide to alter natural β -AP aggregation and/or may confer additional beneficial properties on the peptide (e.g., increased solubility, reduced association with other amyloid proteins, etc.). For example, substitution of hydrophobic amino acid residues for the two phenylalanine residues at positions 19 and 20 of natural β -AP (positions 19 and 20 of the amino acid sequence shown in SEQ ID NO: 1) may further contribute to the ability of the peptide to alter β -AP aggregation (see Hilbich, C. (1992) *J. Mol. Biol.* 228:460-473). Thus, in one embodiment, the β -AP of the compound consists of the amino acid sequence shown below and in SEQ ID NO: 3:

DAEFRHDSGYEVHHQKLV(Xaa₁₉)(Xaa₂₀)AEDVGSNKGAIIGLMVGGVVIAT

(or an amino-terminal or carboxy-terminal deletion thereof), wherein Xaa is a hydrophobic amino acid. Examples of hydrophobic amino acids are isoleucine, leucine, threonine, serine, alanine, valine or glycine. Preferably, F₁₉F₂₀ is substituted with T₁₉T₂₀ or G₁₉I₂₀.

Other suitable amino acid substitutions include replacement of amino acids in the human peptide with the corresponding amino acids of the rodent β -AP peptide. The three amino acid residues that differ between human and rat β -AP are at positions 5, 10 and 13 of the amino acid sequence shown in SEQ ID NOS: 1 and 3. A human β -AP having the human to rodent substitutions Arg₅ to Gly, Tyr₁₀ to Phe and His₁₃ to Arg has been shown to retain the properties of the human peptide (see Fraser, P.E. *et al.* (1992) *Biochemistry* 31:10716-10723; and Hilbich, C. *et al.* (1991) *Eur. J. Biochem.* 201:61-69). Accordingly, a human β -AP having rodent β -AP a.a. substitutions is suitable for use in a modulator of the invention.

Other possible β -AP amino acid substitutions are described in Hilbich, C. *et al.* (1991) *J. Mol. Biol.* 218:149-163; and Hilbich, C. (1992) *J. Mol. Biol.* 228:460-473.

Moreover, amino acid substitutions that affect the ability of β -AP to associate with other proteins can be introduced. For example, one or more amino acid substitutions that reduce the ability of β -AP to associate with the serpin enzyme complex (SEC) receptor, α 1-antichymotrypsin (ACT) and/or apolipoprotein E (ApoE) can be introduced. A preferred substitution for reducing binding to the SEC receptor is L₃₄M₃₅ to A₃₄A₃₅ (at positions 34 and 35 of the amino acid sequences shown in SEQ ID NOS: 1 and 3). A preferred substitution for reducing binding to ACT is S₈ to A₈ (at position 8 of the amino acid sequences shown in SEQ ID NOS: 1 and 3).

Alternative to β -AP amino acid substitutions described herein or known in the art, a modulator composed, at least in part, of an amino acid-substituted β amyloid peptide can be prepared by standard techniques and tested for the ability to alter β -AP aggregation using an aggregation assay described herein. To retain the properties of the original modulator, preferably conservative amino acid substitutions are made at one or more amino acid residues. A "conservative amino acid substitution" is one in which the amino acid residue is

replaced with an amino acid residue having a similar side chain. Families of amino acid residues having similar side chains have been defined in the art, including basic side chains (e.g., lysine, arginine, histidine), acidic side chains (e.g., aspartic acid, glutamic acid), uncharged polar side chains (e.g., glycine, asparagine, glutamine, serine, threonine, tyrosine, cysteine), nonpolar side chains (e.g., alanine, valine, leucine, isoleucine, proline, phenylalanine, methionine, tryptophan), β -branched side chains (e.g., threonine, valine, isoleucine) and aromatic side chains (e.g., tyrosine, phenylalanine, tryptophan, histidine). Accordingly, a modulator composed of a β amyloid peptide having an amino acid sequence that is mutated from that of the wild-type sequence in APP-770 yet which still retains the ability to alter natural β -AP aggregation is within the scope of the invention.

As used herein, the term " β amyloid peptide" is further intended to include peptide analogues or peptide derivatives or peptidomimetics that retain the ability to alter natural β -AP aggregation as described herein. For example, a β amyloid peptide of a modulator of the invention may be modified to increase its stability, bioavailability, solubility, etc. The terms "peptide analogue", "peptide derivative" and "peptidomimetic" as used herein are intended to include molecules which mimic the chemical structure of a peptide and retain the functional properties of the peptide. Approaches to designing peptide analogs are known in the art. For example, see Farmer, P.S. in Drug Design (E.J. Ariens, ed.) Academic Press, New York, 1980, vol. 10, pp. 119-143; Ball, J.B. and Alewood, P.F. (1990) *J. Mol. Recognition* 3:55; Morgan, B.A. and Gainor, J.A. (1989) *Ann. Rep. Med. Chem.* 24:243; and Freidinger, R.M. (1989) *Trends Pharmacol. Sci.* 10:270. Examples of peptide analogues, derivatives and peptidomimetics include peptides substituted with one or more benzodiazepine molecules (see e.g., James, G.L. et al. (1993) *Science* 260:1937-1942), peptides with methylated amide linkages and "retro-inverso" peptides (see U.S. Patent No. 4,522,752 by Sisto). Peptide analogues, peptide derivatives and peptidomimetic are described in further detail below with regard to compounds comprising an A β aggregation core domain.

In a modulator of the invention having the formula shown above, a modulating group ("A") is attached directly or indirectly to the β -amyloid peptide of the modulator (As used herein, the term "modulating group" and "modifying group" are used interchangeably to describe a chemical group directly or indirectly attached to an A β derived peptidic structure). For example, the modulating group can be directly attached by covalent coupling to the β -amyloid peptide or the modulating group can be attached indirectly by a stable non-covalent association. In one embodiment of the invention, the modulating group is attached to the amino-terminus of the β -amyloid peptide of the modulator. Accordingly, the modulator can comprise a compound having a formula:

Alternatively, in another embodiment of the invention, the modulating group is attached to the carboxy-terminus of the β -amyloid peptide of the modulator. Accordingly, the modulator can comprise a compound having a formula:

In yet another embodiment, the modulating group is attached to the side chain of at least one amino acid residues of the β -amyloid peptide of the compound (*e.g.*, through the epsilon amino group of a lysyl residue(s), through the carboxyl group of an aspartic acid residue(s) or a glutamic acid residue(s), through a hydroxy group of a tyrosyl residue(s), a serine residue(s) or a threonine residue(s) or other suitable reactive group on an amino acid side chain).

The modulating group is selected such that the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. Accordingly, since the β -AP peptide of the compound is modified from its natural state, the modulating group "A" as used herein is not intended to include hydrogen. In a preferred embodiment, the modulating group is a biotin compound of the formula:

wherein X_1 - X_3 are each independently selected from the group consisting of S, O and NR_2 , wherein R_2 is hydrogen, or an aryl, lower alkyl, alkenyl or alkynyl moiety; W is $=O$ or NR_2 ; R_1 is a lower alkylene moiety and Y is a direct bond or a spacer molecule selected for its ability to react with a target group on a β -AP. At least one of X_1 - X_3 or W is an NR_2 group.

The term "aryl" is intended to include aromatic moieties containing substituted or unsubstituted ring(s), *e.g.*, benzyl, naphthyl, etc. Other more complex fused ring moieties also are intended to be included.

The term "lower alkyl or alkylene moiety" refers to a saturated, straight or branched chain (or combination thereof) hydrocarbon containing 1 to about 6 carbon atoms, more preferably from 1 to 3 carbon atoms. The terms "lower alkenyl moiety" and "lower alkynyl moiety" refer to unsaturated hydrocarbons containing 1 to about 6 carbon atoms, more preferably 1 to 3 carbon atoms. Preferably, R_2 contains 1 to 3 carbon atoms. Preferably, R_1 contains 4 carbon atoms.

The spacer molecule (Y) can be, for example, a lower alkyl group or a linker peptide, and is preferably selected for its ability to link with a free amino group (*e.g.*, the α -amino group at the amino-terminus of a β -AP). Thus, in a preferred embodiment, the biotin compound modifies the amino-terminus of a β -amyloid peptide.

5 Additional suitable modulating groups may include other cyclic and heterocyclic compounds and other compounds having similar steric "bulk". Non-limiting examples of compounds which can be used to modify a β -AP are shown schematically in Figure 2, and include *N*-acetylneuraminic acid, cholic acid, *trans*-4-cotininecarboxylic acid, 2-imino-1-imidazolidineacetic acid, (*S*)-(-)-indoline-2-carboxylic acid, (-)-menthoxyacetic acid, 2-
10 norbornaneacetic acid, γ -oxo-5-acenaphthenebutyric acid, (-)-2-oxo-4-thiazolidinecarboxylic acid, tetrahydro-3-furoic acid, 2-iminobiotin-*N*-hydroxysuccinimide ester, diethylenetriaminepentaacetic dianhydride, 4-morpholinecarbonyl chloride, 2-thiopheneacetyl chloride, 2-thiophenesulfonyl chloride, 5-(and 6)-carboxyfluorescein (succinimidyl ester), fluorescein isothiocyanate, and acetic acid (or derivatives thereof).
15 Suitable modulating groups are described further in subsection II below.

In a modulator of the invention, a single modulating group may be attached to a β -amyloid peptide (*e.g.*, $n=1$ in the formula shown above) or multiple modulating groups may be attached to the peptide. The number of modulating groups is selected such that the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural
20 β -amyloid peptides. However, n preferably is an integer between 1 and 60, more preferably between 1 and 30 and even more preferably between 1 and 10 or 1 and 5.

In another embodiment, a β -amyloid modulator compound of the invention comprises an A β aggregation core domain (abbreviated as ACD) coupled directly or indirectly to a
25 modifying group such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. As used herein, an "A β aggregation core domain" is intended to refer to a structure that is modeled after a subregion of a natural β -amyloid peptide which is sufficient to modulate aggregation of natural β -APs when this subregion of the natural β -AP is
30 appropriately modified as described herein (*e.g.*, modified at the amino-terminus). The term "subregion of a natural β -amyloid peptide" is intended to include amino-terminal and/or carboxy-terminal deletions of natural β -AP. The term "subregion of natural β -AP" is not intended to include full-length natural β -AP (*i.e.*, "subregion" does not include A β ₁₋₃₉, A β ₁₋₄₀, A β ₁₋₄₁, A β ₁₋₄₂ and A β ₁₋₄₃).

35 Although not intending to be limited by mechanism, the ACD of the modulators of the invention is thought to confer a specific targeting function on the compound that allows the compound to recognize and specifically interact with natural β -AP. Preferably, the ACD is modeled after a subregion of natural β -AP that is less than 15 amino acids in length and more preferably is between 3-10 amino acids in length. In various embodiments, the ACD is

modeled after a subregion of β -AP that is 10, 9, 8, 7, 6, 5, 4 or 3 amino acids in length. In one embodiment, the subregion of β -AP upon which the ACD is modeled is an internal or carboxy-terminal region of β -AP (*i.e.*, downstream of the amino-terminus at amino acid position 1). In another embodiment, the ACD is modeled after a subregion of β -AP that is hydrophobic. In certain specific embodiments, the term A β aggregation core domain specifically excludes β -AP subregions corresponding to amino acid positions 1-15 (A β ₁₋₁₅), 6-20 (A β ₆₋₂₀) and 16-40 (A β ₁₆₋₄₀).

An A β aggregation core domain can be comprised of amino acid residues linked by peptide bonds. That is, the ACD can be a peptide corresponding to a subregion of β -AP. Alternatively, an A β aggregation core domain can be modeled after the natural A β peptide region but may be comprised of a peptide analogue, peptide derivative or peptidomimetic compound, or other similar compounds which mimics the structure and function of the natural peptide. Accordingly, as used herein, an "A β aggregation core domain" is intended to include peptides, peptide analogues, peptide derivatives and peptidomimetic compounds which, when appropriately modified, retain the aggregation modulatory activity of the modified natural A β peptide subregion. Such structures that are designed based upon the amino acid sequence are referred to herein as "A β derived peptidic structures." Approaches to designing peptide analogues, derivatives and mimetics are known in the art. For example, see Farmer, P.S. in Drug Design (E.J. Ariens, ed.) Academic Press, New York, 1980, vol. 10, pp. 119-143; Ball, J.B. and Alewood, P.F. (1990) *J. Mol. Recognition* 3:55; Morgan, B.A. and Gainor, J.A. (1989) *Ann. Rep. Med. Chem.* 24:243; and Freidinger, R.M. (1989) *Trends Pharmacol. Sci.* 10:270. See also Sawyer, T.K. (1995) "Peptidomimetic Design and Chemical Approaches to Peptide Metabolism" in Taylor, M.D. and Amidon, G.L. (eds.) Peptide-Based Drug Design: Controlling Transport and Metabolism. Chapter 17: Smith, A.B. 3rd. *et al.* (1995) *J. Am. Chem. Soc.* 117:11113-11123; Smith, A.B. 3rd. *et al.* (1994) *J. Am. Chem. Soc.* 116:9947-9962; and Hirschman, R., *et al.* (1993) *J. Am. Chem. Soc.* 115:12550-12568.

As used herein, a "derivative" of a compound X (*e.g.*, a peptide or amino acid) refers to a form of X in which one or more reaction groups on the compound have been derivatized with a substituent group. Examples of peptide derivatives include peptides in which an amino acid side chain, the peptide backbone, or the amino- or carboxy-terminus has been derivatized (*e.g.*, peptidic compounds with methylated amide linkages). As used herein an "analogue" of a compound X refers to a compound which retains chemical structures of X necessary for functional activity of X yet which also contains certain chemical structures which differ from X. An examples of an analogue of a naturally-occurring peptide is a peptides which includes one or more non-naturally-occurring amino acids. As used herein, a "mimetic" of a compound X refers to a compound in which chemical structures of X necessary for functional activity of X have been replaced with other chemical structures which mimic the conformation of X. Examples of peptidomimetics include peptidic

compounds in which the peptide backbone is substituted with one or more benzodiazepine molecules (see *e.g.*, James, G.L. *et al.* (1993) *Science* 260:1937-1942), peptides in which all L-amino acids are substituted with the corresponding D-amino acids and "retro-inverso" peptides (see U.S. Patent No. 4,522,752 by Sisto), described further below.

5 The term mimetic, and in particular, peptidomimetic, is intended to include isosteres. The term "isostere" as used herein is intended to include a chemical structure that can be substituted for a second chemical structure because the steric conformation of the first structure fits a binding site specific for the second structure. The term specifically includes peptide back-bone modifications (*i.e.*, amide bond mimetics) well known to those skilled in
10 the art. Such modifications include modifications of the amide nitrogen, the α -carbon, amide carbonyl, complete replacement of the amide bond, extensions, deletions or backbone crosslinks. Several peptide backbone modifications are known, including $\psi[\text{CH}_2\text{S}]$, $\psi[\text{CH}_2\text{NH}]$, $\psi[\text{CSNH}_2]$, $\psi[\text{NHCO}]$, $\psi[\text{COCH}_2]$, and $\psi[(\text{E}) \text{ or } (\text{Z}) \text{ CH}=\text{CH}]$. In the nomenclature used above, ψ indicates the absence of an amide bond. The structure that
15 replaces the amide group is specified within the brackets. Other examples of isosteres include peptides substituted with one or more benzodiazepine molecules (see *e.g.*, James, G.L. *et al.* (1993) *Science* 260:1937-1942)

Other possible modifications include an N-alkyl (or aryl) substitution ($\psi[\text{CONR}]$), backbone crosslinking to construct lactams and other cyclic structures, substitution of all D-
20 amino acids for all L-amino acids within the compound ("inverso" compounds) or retro-inverso amino acid incorporation ($\psi[\text{NHCO}]$). By "inverso" is meant replacing L-amino acids of a sequence with D-amino acids, and by "retro-inverso" or "enantio-retro" is meant reversing the sequence of the amino acids ("retro") and replacing the L-amino acids with D-
25 amino acids. For example, if the parent peptide is Thr-Ala-Tyr, the retro modified form is Tyr-Ala-Thr, the inverso form is thr-ala-tyr, and the retro-inverso form is tyr-ala-thr (lower case letters refer to D-amino acids). Compared to the parent peptide, a retro-inverso peptide has a reversed backbone while retaining substantially the original spatial conformation of the side chains, resulting in a retro-inverso isomer with a topology that closely resembles the parent peptide. See Goodman *et al.* "Perspectives in Peptide Chemistry" pp. 283-294
30 (1981). See also U.S. Patent No. 4,522,752 by Sisto for further description of "retro-inverso" peptides.

Other derivatives of the modulator compounds of the invention include C-terminal hydroxymethyl derivatives, O-modified derivatives (*e.g.*, C-terminal hydroxymethyl benzyl ether), N-terminally modified derivatives including substituted amides such as alkylamides
35 and hydrazides and compounds in which a C-terminal phenylalanine residue is replaced with a phenethylamide analogue (*e.g.*, Val-Phe-phenethylamide as an analogue of the tripeptide Val-Phe-Phe).

In a preferred embodiment, the ACD of the modulator is modeled after the subregion of β -AP encompassing amino acid positions 17-20 (*i.e.*, Leu-Val-Phe-Phe; SEQ ID NO: 12).

14

As described further in Examples 7, 8 and 9, peptide subregions of $A\beta_{1-40}$ were prepared, amino-terminally modified and evaluated for their ability to modulate aggregation of natural β -amyloid peptides. One subregion that was effective at inhibiting aggregation was $A\beta_{6-20}$ (*i.e.*, amino acid residues 6-20 of the natural $A\beta_{1-40}$ peptide, the amino acid sequence of which is shown in SEQ ID NO: 4). Amino acid residues were serially deleted from the amino-terminus or carboxy terminus of this subregion to further delineate a minimal subregion that was sufficient for aggregation inhibitory activity. This process defined $A\beta_{17-20}$ (*i.e.*, amino acid residues 17-20 of the natural $A\beta_{1-40}$ peptide) as a minimal subregion that, when appropriately modified, is sufficient for aggregation inhibitory activity. Accordingly, an "A β aggregation core domain" within a modulator compound of the invention can be modeled after $A\beta_{17-20}$. In one embodiment, the A β aggregation core domain comprises $A\beta_{17-20}$ itself (*i.e.*, a peptide comprising the amino acid sequence leucine-valine-phenylalanine-phenylalanine; SEQ ID NO: 12). In other embodiments, the structure of $A\beta_{17-20}$ is used as a model to design an A β aggregation core domain having similar structure and function to $A\beta_{17-20}$. For example, peptidomimetics, derivatives or analogues of $A\beta_{17-20}$ (as described above) can be used as an A β aggregation core domain. In addition to $A\beta_{17-20}$, the natural A β peptide is likely to contain other minimal subregions that are sufficient for aggregation inhibitory activity. Such additional minimal subregions can be identified by the processes described in Examples 7, 8 and 9, wherein a 15mer subregion of $A\beta_{1-40}$ is serially deleted from the amino-terminus or carboxy terminus, the deleted peptides are appropriately modified and then evaluated for aggregation inhibitory activity.

One form of the β -amyloid modulator compound comprising an A β aggregation core domain modeled after $A\beta_{17-20}$ coupled directly or indirectly to at least one modifying group has the formula:

wherein Xaa_1 and Xaa_3 are amino acid structures;

Xaa_2 is a valine structure;

Xaa_4 is a phenylalanine structure;

Y, which may or may not be present, is a peptidic structure having the formula $(Xaa)_a$, wherein Xaa is any amino acid structure and a is an integer from 1 to 15;

Z, which may or may not be present, is a peptidic structure having the formula $(Xaa)_b$, wherein Xaa is any amino acid structure and b is an integer from 1 to 15; and

A is a modifying group attached directly or indirectly to the compound and n is an integer;

Xaa_1 , Xaa_3 , Y, Z, A and n being selected such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

Preferably, a modulator compound of the above formula inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides and/or inhibits $A\beta$ neurotoxicity. Alternatively, the modulator compound can promote aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. The type and number of modifying groups ("A") coupled to the modulator are selected such that the compound alters (and preferably inhibits) aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. A single modifying group can be coupled to the modulator (*i.e.*, $n=1$ in the above formula) or, alternatively, multiple modifying groups can be coupled to the modulator. In various embodiments, n is an integer between 1 and 60, between 1 and 30, between 1 and 10, between 1 and 5 or between 1 and 3. Suitable types of modifying groups are described further in subsection II below.

As demonstrated in Example 9, amino acid positions 18 (Val₁₈) and 20 (Phe₂₀) of $A\beta_{17-20}$ (corresponding to Xaa₂ and Xaa₄) are particularly important within the core domain for inhibitory activity of the modulator compound. Accordingly, these positions are conserved within the core domain in the formula shown above. The terms "valine structure" and "phenylalanine structure" as used in the above formula are intended to include the natural amino acids, as well as non-naturally-occurring analogues, derivatives and mimetics of valine and phenylalanine, respectively, (including D-amino acids) which maintain the functional activity of the compound. Moreover, although Val₁₈ and Phe₂₀ have an important functional role, it is possible that Xaa₂ and/or Xaa₄ can be substituted with other naturally-occurring amino acids that are structurally related to valine or phenylalanine, respectively, while still maintaining the activity of the compound. Thus, the terms "valine structure" is intended to include conservative amino acid substitutions that retain the activity of valine at Xaa₂, and the term "phenylalanine structure" is intended to include conservative amino acid substitutions that retain the activity of phenylalanine at Xaa₄. However, the term "valine structure" is not intended to include threonine.

In contrast to positions 18 and 20 of $A\beta_{17-20}$, a Phe to Ala substitution at position 19 (corresponding to Xaa₃) did not abolish the activity of the modulator, indicating position 19 may be more amenable to amino acid substitution. In various embodiments of the above formula, positions Xaa₁ and Xaa₃ are any amino acid structure. The term "amino acid structure" is intended to include natural and non-natural amino acids as well as analogues, derivatives and mimetics thereof, including D-amino acids. In a preferred embodiment of the above formula, Xaa₁ is a leucine structure and Xaa₃ is a phenylalanine structure (*i.e.*, modeled after Leu₁₇ and Phe₁₉, respectively, in the natural $A\beta$ peptide sequence). The term "leucine structure" is used in the same manner as valine structure and phenylalanine structure described above. Alternatively, in another embodiment, Xaa₃ is an alanine structure.

The four amino acid structure ACD of the modulator of the above formula can be flanked at the amino-terminal side, carboxy-terminal side, or both, by peptidic structures derived either from the natural $A\beta$ peptide sequence or from non- $A\beta$ sequences. The term

20

"peptidic structure" is intended to include peptide analogues, derivatives and mimetics thereof, as described above. The peptidic structure is composed of one or more linked amino acid structures, the type and number of which in the above formula are variable. For example, in one embodiment, no additional amino acid structures flank the Xaa₁-Xaa₂-Xaa₃-Xaa₄ core sequence (*i.e.*, Y and Z are absent in the above formula). In another embodiment, one or more additional amino acid structures flank only the amino-terminus of the core sequences (*i.e.*, Y is present but Z is absent in the above formula). In yet another embodiment, one or more additional amino acid structures flank only the carboxy-terminus of the core sequences (*i.e.*, Z is present but Y is absent in the above formula). The length of flanking Z or Y sequences also is variable. For example, in one embodiment, a and b are integers from 1 to 15. More preferably, a and b are integers between 1 and 10. Even more preferably, a and b are integers between 1 and 5. Most preferably, a and b are integers between 1 and 3.

One form of the β -amyloid modulator compound comprising an A β aggregation core domain modeled after A β ₁₇₋₂₀ coupled directly or indirectly to at least one modifying group has the formula:

wherein Xaa₁ and Xaa₃ are amino acids or amino acid mimetics;

Xaa₂ is valine or a valine mimetic

Xaa₄ is phenylalanine or a phenylalanine mimetic;

Y, which may or may not be present, is a peptide or peptidomimetic having the formula (Xaa)_a, wherein Xaa is any amino acid or amino acid mimetic and a is an integer from 1 to 15;

Z, which may or may not be present, is a peptide or peptidomimetic having the formula (Xaa)_b, wherein Xaa is any amino acid or amino acid mimetic and b is an integer from 1 to 15; and

A and B, at least one of which is present, are modifying groups attached directly or indirectly to the amino terminus and carboxy terminus, respectively, of the compound;

Xaa₁, Xaa₃, Y, Z, A and B being selected such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

In this embodiment, the modulator compound is specifically modified at either its amino-terminus, its carboxy-terminus, or both. The terminology used in this formula is the same as described above. Suitable modifying groups are described in subsection II below. In one embodiment, the compound is modified only at its amino terminus (*i.e.*, B is absent and the compound comprises the formula: A-(Y)-Xaa₁-Xaa₂-Xaa₃-Xaa₄-(Z)). In another embodiment, the compound is modified only at its carboxy-terminus (*i.e.*, A is absent and the

compound comprises the formula: (Y)-Xaa₁-Xaa₂-Xaa₃-Xaa₄-(Z)-B). In yet another embodiment, the compound is modified at both its amino- and carboxy termini (*i.e.*, the compound comprises the formula: A-(Y)-Xaa₁-Xaa₂-Xaa₃-Xaa₄-(Z)-B and both A and B are present). As described above, the type and number of amino acid structures which flank the Xaa₁-Xaa₂-Xaa₃-Xaa₄ core sequences in the above formula is variable. For example, in one embodiment, a and b are integers from 1 to 15. More preferably, a and b are integers between 1 and 10. Even more preferably, a and b are integers between 1 and 5. Most preferably, a and b are integers between 1 and 3.

As demonstrated in Examples 7, 8 and 9, preferred A β modulator compounds of the invention comprise modified forms of A β ₁₄₋₂₁ (His-Gln-Lys-Leu-Val-Phe-Phe-Ala; SEQ ID NO: 5), or amino-terminal or carboxy-terminal deletions thereof, with a preferred "minimal core region" comprising A β ₁₇₋₂₀. Accordingly, in specific embodiments, the invention provides compounds comprising the formula:

wherein Xaa1 is a histidine structure;

Xaa2 is a glutamine structure;

Xaa3 is a lysine structure;

Xaa4 is a leucine structure;

Xaa5 is a valine structure;

Xaa6 is a phenylalanine structure;

Xaa7 is a phenylalanine structure;

Xaa8 is an alanine structure;

A and B are modifying groups attached directly or indirectly to the amino terminus and carboxy terminus, respectively, of the compound;

and wherein Xaa₁-Xaa₂-Xaa₃, Xaa₁-Xaa₂ or Xaa₁ may or may not be present;

Xaa₈ may or may not be present; and

at least one of A and B is present.

In one specific embodiment, the compound comprises the formula: A-Xaa₄-Xaa₅-Xaa₆-Xaa₇-B (e.g., a modified form of A β ₁₇₋₂₀, comprising an amino acid sequence Leu-Val-Phe-Phe; SEQ ID NO: 12).

In another specific embodiment, the compound comprises the formula: A-Xaa₄-Xaa₅-Xaa₆-Xaa₇-Xaa₈-B (e.g., a modified form of A β ₁₇₋₂₁, comprising an amino acid sequence Leu-Val-Phe-Phe-Ala; SEQ ID NO: 11).

In another specific embodiment, the compound comprises the formula: A-Xaa₃-Xaa₄-Xaa₅-Xaa₆-Xaa₇-B (e.g., a modified form of A β ₁₆₋₂₀, comprising an amino acid sequence Lys-Leu-Val-Phe-Phe; SEQ ID NO: 10).

22

In another specific embodiment, the compound comprises the formula: A-Xaa₃-Xaa₄-Xaa₅-Xaa₆-Xaa₇-Xaa₈-B (*e.g.*, a modified form of A β ₁₆₋₂₁, comprising an amino acid sequence Lys-Leu-Val-Phe-Phe-Ala; SEQ ID NO: 9).

5 In another specific embodiment, the compound comprises the formula: A-Xaa₂-Xaa₃-Xaa₄-Xaa₅-Xaa₆-Xaa₇-B (*e.g.*, a modified form of A β ₁₅₋₂₀, comprising an amino acid sequence Gln-Lys-Leu-Val-Phe-Phe; SEQ ID NO: 8).

In another specific embodiment, the compound comprises the formula: A-Xaa₂-Xaa₃-Xaa₄-Xaa₅-Xaa₆-Xaa₇-Xaa₈-B (*e.g.*, a modified form of A β ₁₅₋₂₁, comprising an amino acid sequence Gln-Lys-Leu-Val-Phe-Phe-Ala; SEQ ID NO: 7).

10 In another specific embodiment, the compound comprises the formula: A-Xaa₁-Xaa₂-Xaa₃-Xaa₄-Xaa₅-Xaa₆-Xaa₇-B (*e.g.*, a modified form of A β ₁₄₋₂₀, comprising an amino acid sequence His-Gln-Lys-Leu-Val-Phe-Phe; SEQ ID NO: 6).

15 In another specific embodiment, the compound comprises the formula: A-Xaa₁-Xaa₂-Xaa₃-Xaa₄-Xaa₅-Xaa₆-Xaa₇-Xaa₈-B (*e.g.*, a modified form of A β ₁₄₋₂₁, comprising an amino acid sequence His-Gln-Lys-Leu-Val-Phe-Phe-Ala; SEQ ID NO: 5).

In preferred embodiments of the aforementioned specific embodiments, A or B is a cholanoyl structure or a biotin-containing structure (described further in subsection II below).

20 In further experiments to delineate subregions of A β upon which an A β aggregation core domain can be modeled (the results of which are described in Example 11), it was demonstrated that a modulator compound having inhibitory activity can comprise as few as three A β amino acids residues (*e.g.*, Val-Phe-Phe, which corresponds to A β ₁₈₋₂₀ or Phe-Phe-Ala, which corresponds to A β ₁₉₋₂₁). The results also demonstrated that a modulator compound having a modulating group at its carboxy-terminus is effective at inhibiting A β aggregation. Still further, the results demonstrated that the cholyl group, as a modulating group, can be manipulated while maintaining the inhibitory activity of the compounds and that an iodotyrosyl can be substituted for phenylalanine (*e.g.*, at position 19 or 20 of the A β sequence) while maintaining the ability of the compound to inhibit A β aggregation.

25 Still further, the results demonstrated that compounds with inhibitory activity can be created using amino acids residues that are derived from the A β sequence in the region of about positions 17-21 but wherein the amino acid sequence is rearranged or has a substitution with a non-A β -derived amino acid. Examples of such compounds include PPI-426, in which the sequence of A β ₁₇₋₂₁ (LVFFA) has been rearranged (FFVLA), PPI-372, in which the sequence of A β ₁₆₋₂₀ (KLVFF) has been rearranged (FKFVL), and PPI-388, -389 and -390, in which the sequence of A β ₁₇₋₂₁ (LVFFA) has been substituted at position 17, 18 or 19, respectively, with an alanine residue (AVFFA for PPI-388, LAFFA for PPI-389 and LVAFA for PPI-390). The inhibitory activity of these compounds indicate that the presence in the compound of an amino acid sequence directly corresponding to a portion of A β is not essential for inhibitory activity, but rather suggests that maintenance of the hydrophobic

nature of this core region, by inclusion of amino acid residues such as phenylalanine, valine, leucine, regardless of their precise order, can be sufficient for inhibition of A β aggregation. Accordingly, an A β aggregation core domain can be designed based on the direct A β amino acid sequence or can be designed based on a rearranged A β sequence which maintains the hydrophobicity of the A β subregion, *e.g.*, the region around positions 17-20. This region of A β contains the amino acid residues Leu, Val and Phe. Accordingly, preferred A β aggregation core domains are composed of at least three amino acid structures (as that term is defined hereinbefore, including amino acid derivatives, analogues and mimetics), wherein at least two of the amino acid structures are, independently, either a leucine structure, a valine structure or a phenylalanine structure (as those terms are defined hereinbefore, including derivatives, analogues and mimetics).

Thus, in another embodiment, the invention provides a β -amyloid modulator compound comprising a formula:

wherein Xaa₁, Xaa₂ and Xaa₃ are each amino acid structures and at least two of Xaa₁, Xaa₂ and Xaa₃ are, independently, selected from the group consisting of a leucine structure, a phenylalanine structure and a valine structure;

Y, which may or may not be present, is a peptidic structure having the formula (Xaa)_a, wherein Xaa is any amino acid structure and a is an integer from 1 to 15;

Z, which may or may not be present, is a peptidic structure having the formula (Xaa)_b, wherein Xaa is any amino acid structure and b is an integer from 1 to 15; and

A is a modifying group attached directly or indirectly to the compound and n is an integer;

Xaa₁, Xaa₂, Xaa₃, Y, Z, A and n being selected such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

Preferably, the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. In preferred embodiments, Xaa₁ and Xaa₂ are each phenylalanine structures or Xaa₂ and Xaa₃ are each phenylalanine structures. "n" can be, for example, an integer between 1 and 5, whereas "a" and "b" can be, for example, integers between 1 and 5. The modifying group "A" preferably comprises a cyclic, heterocyclic or polycyclic group. More preferably, A contains a cis-decalin group, such as cholanoyl structure or a cholyl group. In other embodiments, A can comprise a biotin-containing group, a diethylene-triaminepentaacetyl group, a (-)-menthoxyacetyl group, a fluorescein-containing group or an N-acetylneuraminyl group. In yet other embodiments, the compound may promotes aggregation of natural β -amyloid peptides when contacted with the

24

natural β -amyloid peptides, may be further modified to alter a pharmacokinetic property of the compound or may be further modified to label the compound with a detectable substance.

In another embodiment, the invention provides a β -amyloid modulator compound comprising a formula:

5

10

wherein Xaa_1 , Xaa_2 and Xaa_3 are each amino acid structures and at least two of Xaa_1 , Xaa_2 and Xaa_3 are, independently, selected from the group consisting of a leucine structure, a phenylalanine structure and a valine structure;

Y, which may or may not be present, is a peptidic structure having the formula $(Xaa)_a$, wherein Xaa is any amino acid structure and a is an integer from 1 to 15;

Z, which may or may not be present, is a peptidic structure having the formula $(Xaa)_b$, wherein Xaa is any amino acid structure and b is an integer from 1 to 15; and

15

A and B, at least one of which is present, are modifying groups attached directly or indirectly to the amino terminus and carboxy terminus, respectively, of the compound;

20

Xaa_1 , Xaa_2 , Xaa_3 , Y, Z, A and B being selected such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

Preferably, the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. In preferred embodiments, Xaa_1 and Xaa_2 are each phenylalanine structures or Xaa_2 and Xaa_3 are each phenylalanine structures. In one subembodiment, the compound comprises the formula:

25

In another subembodiment, the compound comprises the formula:

"n" can be, for example, an integer between 1 and 5, whereas "a" and "b" can be, for example, integers between 1 and 5. The modifying group "A" preferably comprises a cyclic,

30

heterocyclic or polycyclic group. More preferably, A contains a cis-decalin group, such as cholanoyl structure or a cholyl group. In other embodiments, A can comprise a biotin-

containing group, a diethylene-triaminepentaacetyl group, a (-)-menthoxyacetyl group, a fluorescein-containing group or an N-acetylneuraminyl group. In yet other embodiments, the

35

compound may promote aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides, may be further modified to alter a pharmacokinetic property of the compound or may be further modified to label the compound with a detectable substance.

In preferred specific embodiments, the invention provides a β -amyloid modulator compound comprising a modifying group attached directly or indirectly to a peptidic structure, wherein the peptidic structure comprises amino acid structures having an amino

25

acid sequence selected from the group consisting of His-Gln-Lys-Leu-Val-Phe-Phe-Ala (SEQ ID NO: 5), His-Gln-Lys-Leu-Val-Phe-Phe (SEQ ID NO: 6), Gln-Lys-Leu-Val-Phe-Phe-Ala (SEQ ID NO: 7), Gln-Lys-Leu-Val-Phe-Phe (SEQ ID NO: 8), Lys-Leu-Val-Phe-Phe-Ala (SEQ ID NO: 9), Lys-Leu-Val-Phe-Phe (SEQ ID NO: 10), Leu-Val-Phe-Phe-Ala (SEQ ID NO: 11), Leu-Val-Phe-Phe (SEQ ID NO: 12), Leu-Ala-Phe-Phe-Ala (SEQ ID NO: 13), Val-Phe-Phe (SEQ ID NO: 19), Phe-Phe-Ala (SEQ ID NO: 20), Phe-Phe-Val-Leu-Ala (SEQ ID NO: 21), Leu-Val-Phe-Phe-Lys (SEQ ID NO: 22), Leu-Val-Iodotyrosine-Phe-Ala (SEQ ID NO: 23), Val-Phe-Phe-Ala (SEQ ID NO: 24), Ala-Val-Phe-Phe-Ala (SEQ ID NO: 25), Leu-Val-Phe-Iodotyrosine-Ala (SEQ ID NO: 26), Leu-Val-Phe-Phe-Ala-Glu (SEQ ID NO: 27), Phe-Phe-Val-Leu (SEQ ID NO: 28), Phe-Lys-Phe-Val-Leu (SEQ ID NO: 29), Lys-Leu-Val-Ala-Phe (SEQ ID NO: 30), Lys-Leu-Val-Phe-Phe- β Ala (SEQ ID NO: 31) and Leu-Val-Phe-Phe-DAla (SEQ ID NO: 32).

These specific compounds can be further modified to alter a pharmacokinetic property of the compound and/or further modified to label the compound with a detectable substance.

The modulator compounds of the invention can be incorporated into pharmaceutical compositions (described further in subsection V below) and can be used in detection and treatment methods as described further in subsection VI below.

II. Modifying Groups

Within a modulator compound of the invention, a peptidic structure (such as an A β derived peptide, or an A β aggregation core domain, or an amino acid sequence corresponding to a rearranged A β aggregation core domain) is coupled directly or indirectly to at least one modifying group (abbreviated as MG). In one embodiment, a modulator compounds of the invention comprising an aggregation core domain coupled to a modifying group, the compound can be illustrated schematically as MG-ACD. The term "modifying group" is intended to include structures that are directly attached to the peptidic structure (*e.g.*, by covalent coupling), as well as those that are indirectly attached to the peptidic structure (*e.g.*, by a stable non-covalent association or by covalent coupling to additional amino acid residues, or mimetics, analogues or derivatives thereof, which may flank the A β -derived peptidic structure). For example, the modifying group can be coupled to the amino-terminus or carboxy-terminus of an A β -derived peptidic structure, or to a peptidic or peptidomimetic region flanking the core domain. Alternatively, the modifying group can be coupled to a side chain of at least one amino acid residue of an A β -derived peptidic structure, or to a peptidic or peptidomimetic region flanking the core domain (*e.g.*, through the epsilon amino group of a lysyl residue(s), through the carboxyl group of an aspartic acid residue(s) or a glutamic acid residue(s), through a hydroxy group of a tyrosyl residue(s), a serine residue(s) or a threonine residue(s) or other suitable reactive group on an amino acid side chain). Modifying groups covalently coupled to the peptidic structure can be attached by means and using methods well

known in the art for linking chemical structures, including, for example, amide, alkylamino, carbamate or urea bonds.

The term "modifying group" is intended to include groups that are not naturally coupled to natural A β peptides in their native form. Accordingly, the term "modifying group" is not intended to include hydrogen. The modifying group(s) is selected such that the modulator compound alters, and preferably inhibits, aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. Although not intending to be limited by mechanism, the modifying group(s) of the modulator compounds of the invention is thought to function as a key pharmacophore which is important for conferring on the modulator the ability to disrupt A β polymerization.

In a preferred embodiment, the modifying group(s) comprises a cyclic, heterocyclic or polycyclic group. The term "cyclic group", as used herein, is intended to include cyclic saturated or unsaturated (*i.e.*, aromatic) group having from about 3 to 10, preferably about 4 to 8, and more preferably about 5 to 7, carbon atoms. Exemplary cyclic groups include cyclopropyl, cyclobutyl, cyclopentyl, cyclohexyl, and cyclooctyl. Cyclic groups may be unsubstituted or substituted at one or more ring positions. Thus, a cyclic group may be substituted with, *e.g.*, halogens, alkyls, cycloalkyls, alkenyls, alkynyls, aryls, heterocycles, hydroxyls, aminos, nitros, thiols amines, imines, amides, phosphonates, phosphines, carbonyls, carboxyls, silyls, ethers, thioethers, sulfonyls, sulfonates, selenoethers, ketones, aldehydes, esters, -CF₃, -CN, or the like.

The term "heterocyclic group" is intended to include cyclic saturated or unsaturated (*i.e.*, aromatic) group having from about 3 to 10, preferably about 4 to 8, and more preferably about 5 to 7, carbon atoms, wherein the ring structure includes about one to four heteroatoms. Heterocyclic groups include pyrrolidine, oxolane, thiolane, imidazole, oxazole, piperidine, piperazine, morpholine. The heterocyclic ring can be substituted at one or more positions with such substituents as, for example, halogens, alkyls, cycloalkyls, alkenyls, alkynyls, aryls, other heterocycles, hydroxyl, amino, nitro, thiol, amines, imines, amides, phosphonates, phosphines, carbonyls, carboxyls, silyls, ethers, thioethers, sulfonyls, selenoethers, ketones, aldehydes, esters, -CF₃, -CN, or the like. Heterocycles may also be bridged or fused to other cyclic groups as described below.

The term "polycyclic group" as used herein is intended to refer to two or more saturated or unsaturated (*i.e.*, aromatic) cyclic rings in which two or more carbons are common to two adjoining rings, *e.g.*, the rings are "fused rings". Rings that are joined through non-adjacent atoms are termed "bridged" rings. Each of the rings of the polycyclic group can be substituted with such substituents as described above, as for example, halogens, alkyls, cycloalkyls, alkenyls, alkynyls, hydroxyl, amino, nitro, thiol, amines, imines, amides, phosphonates, phosphines, carbonyls, carboxyls, silyls, ethers, thioethers, sulfonyls, selenoethers, ketones, aldehydes, esters, -CF₃, -CN, or the like.

A preferred polycyclic group is a group containing a cis-decalin structure. Although not intending to be limited by mechanism, it is thought that the "bent" conformation conferred on a modifying group by the presence of a cis-decalin structure contributes to the efficacy of the modifying group in disrupting A β polymerization. Accordingly, other structures which mimic the "bent" configuration of the cis-decalin structure can also be used as modifying groups. An example of a cis-decalin containing structure that can be used as a modifying group is a cholanoyl structure, such as a cholyl group. For example, a modulator compound can be modified at its amino terminus with a cholyl group by reacting the aggregation core domain with cholic acid, a bile acid, as described in Example 4 (the structure of cholic acid is illustrated in Figure 2). Moreover, a modulator compound can be modified at its carboxy terminus with a cholyl group according to methods known in the art (see e.g., Wess, G. *et al.* (1993) *Tetrahedron Letters*, **34**:817-822; Wess, G. *et al.* (1992) *Tetrahedron Letters* **33**:195-198; and Kramer, W. *et al.* (1992) *J. Biol. Chem.* **267**:18598-18604). Cholyl derivatives and analogues can also be used as modifying groups. For example, a preferred cholyl derivative is Aic (3-(*O*-aminoethyl-*iso*)-cholyl), which has a free amino group that can be used to further modify the modulator compound (e.g., a chelation group for ^{99m}Tc can be introduced through the free amino group of Aic). As used herein, the term "cholanoyl structure" is intended to include the cholyl group and derivatives and analogues thereof, in particular those which retain a four-ring cis-decalin configuration. Examples of cholanoyl structures include groups derived from other bile acids, such as deoxycholic acid, lithocholic acid, ursodeoxycholic acid, chenodeoxycholic acid and hyodeoxycholic acid, as well as other related structures such as cholanic acid, bufalin and resibufogenin (although the latter two compounds are not preferred for use as a modifying group). Another example of a cis-decalin containing compound is 5 β -cholestan-3 α -ol (the cis-decalin isomer of (+)-dihydrocholesterol). For further description of bile acid and steroid structure and nomenclature, see Nes, W.R. and McKean, M.L. *Biochemistry of Steroids and Other Isopentanoids*, University Park Press, Baltimore, MD, Chapter 2.

In addition to cis-decalin containing groups, other polycyclic groups may be used as modifying groups. For example, modifying groups derived from steroids or β -lactams may be suitable modifying groups. Moreover, non-limiting examples of some additional cyclic, heterocyclic or polycyclic compounds which can be used to modify an A β -derived peptidic structure are shown schematically in Figure 2. In one embodiment, the modifying group is a "biotinyl structure", which includes biotinyl groups and analogues and derivatives thereof (such as a 2-iminobiotinyl group). In another embodiment, the modifying group can comprise a "fluorescein-containing group", such as a group derived from reacting an A β -derived peptidic structure with 5-(and 6-)-carboxyfluorescein, succinimidyl ester or fluorescein isothiocyanate. In various other embodiments, the modifying group(s) can comprise an *N*-acetylneuraminyl group, a *trans*-4-cotininecarboxyl group, a 2-imino-1-imidazolidineacetyl group, an (*S*)-(-)-indoline-2-carboxyl group, a (-)-menthoxyacetyl group,

23

a 2-norbornaneacetyl group, a γ -oxo-5-acenaphthenebutyryl, a (-)-2-oxo-4-thiazolidinecarboxyl group, a tetrahydro-3-furoyl group, a 2-iminobiotinyl group, a diethylenetriaminepentaacetyl group, a 4-morpholinecarbonyl group, a 2-thiopheneacetyl group or a 2-thiophenesulfonyl group.

5 Preferred modifying groups include groups comprising cholyl structures, biotinyl structures, fluorescein-containing groups, a diethylene-triaminepentaacetyl group, a (-)-menthoxyacetyl group, and a N-acetylneuraminyl group. More preferred modifying groups those comprising a cholyl structure or an iminobiotinyl group.

10 In addition to the cyclic, heterocyclic and polycyclic groups discussed above, other types of modifying groups can be used in a modulator of the invention. For example, small hydrophobic groups may be suitable modifying groups. An example of a suitable non-cyclic modifying group is an acetyl group.

Yet another type of modifying group is a compound that contains a non-natural amino acid that acts as a beta-turn mimetic, such as a dibenzofuran-based amino acid described in
15 Tsang, K.Y. et al. (1994) *J. Am. Chem. Soc.* 116:3988-4005; Diaz, H and Kelly, J.W. (1991) *Tetrahedron Letters* 41:5725-5728; and Diaz, H et al. (1992) *J. Am. Chem. Soc.* 114:8316-8318. An example of such a modifying group is a peptide-aminoethyldibenzofuranyl-propionic acid (Adp) group (e.g., DDIL-Adp). This type of modifying group further can comprise one or more N-methyl peptide bonds to introduce additional steric hindrance to the
20 aggregation of natural β -AP when compounds of this type interact with natural β -AP.

III. Additional Chemical Modifications of A β Modulators

A β -amyloid modulator compound of the invention can be further modified to alter the specific properties of the compound while retaining the ability of the compound to alter
25 A β aggregation and inhibit A β neurotoxicity. For example, in one embodiment, the compound is further modified to alter a pharmacokinetic property of the compound, such as *in vivo* stability or half-life. In another embodiment, the compound is further modified to label the compound with a detectable substance. In yet another embodiment, the compound is further modified to couple the compound to an additional therapeutic moiety.
30 Schematically, a modulator of the invention comprising an A β aggregation core domain coupled directly or indirectly to at least one modifying group can be illustrated as MG-ACD, whereas this compound which has been further modified to alter the properties of the modulator can be illustrated as MG-ACD-CM, wherein CM represents an additional chemical modification.

35 To further chemically modify the compound, such as to alter the pharmacokinetic properties of the compound, reactive groups can be derivatized. For example, when the modifying group is attached to the amino-terminal end of the aggregation core domain, the carboxy-terminal end of the compound can be further modified. Preferred C-terminal modifications include those which reduce the ability of the compound to act as a substrate for

carboxypeptidases. Examples of preferred C-terminal modifiers include an amide group, an ethylamide group and various non-natural amino acids, such as D-amino acids and β -alanine. Alternatively, when the modifying group is attached to the carboxy-terminal end of the aggregation core domain, the amino-terminal end of the compound can be further modified, for example, to reduce the ability of the compound to act as a substrate for aminopeptidases.

A modulator compound can be further modified to label the compound by reacting the compound with a detectable substance. Suitable detectable substances include various enzymes, prosthetic groups, fluorescent materials, luminescent materials and radioactive materials. Examples of suitable enzymes include horseradish peroxidase, alkaline phosphatase, β -galactosidase, or acetylcholinesterase; examples of suitable prosthetic group complexes include streptavidin/biotin and avidin/biotin; examples of suitable fluorescent materials include umbelliferone, fluorescein, fluorescein isothiocyanate, rhodamine, dichlorotriazinylamine fluorescein, dansyl chloride or phycoerythrin; an example of a luminescent material includes luminol; and examples of suitable radioactive material include ^{14}C , ^{123}I , ^{124}I , ^{125}I , ^{131}I , $^{99\text{m}}\text{Tc}$, ^{35}S or ^3H . In a preferred embodiment, a modulator compound is radioactively labeled with ^{14}C , either by incorporation of ^{14}C into the modifying group or one or more amino acid structures in the modulator compound. Labeled modulator compounds can be used to assess the *in vivo* pharmacokinetics of the compounds, as well as to detect A β aggregation, for example for diagnostic purposes. A β aggregation can be detected using a labeled modulator compound either *in vivo* or in an *in vitro* sample derived from a subject.

Preferably, for use as an *in vivo* diagnostic agent, a modulator compound of the invention is labeled with radioactive technetium or iodine. Accordingly, in one embodiment, the invention provides a modulator compound labeled with technetium, preferably $^{99\text{m}}\text{Tc}$. Methods for labeling peptide compounds with technetium are known in the art (see *e.g.*, U.S. Patent Nos. 5,443,815, 5,225,180 and 5,405,597, all by Dean *et al.*; Stepniak-Biniakiewicz, D., *et al.* (1992) *J. Med. Chem.* **35**:274-279; Fritzberg, A.R., *et al.* (1988) *Proc. Natl. Acad. Sci. USA* **85**:4025-4029; Baidoo, K.E., *et al.* (1990) *Cancer Res. Suppl.* **50**:799s-803s; and Regan, L. and Smith, C.K. (1995) *Science* **270**:980-982). A modifying group can be chosen that provides a site at which a chelation group for $^{99\text{m}}\text{Tc}$ can be introduced, such as the Aic derivative of cholic acid, which has a free amino group (see Example 11). In another embodiment, the invention provides a modulator compound labeled with radioactive iodine. For example, a phenylalanine residue within the A β sequence (such as Phe₁₉ or Phe₂₀) can be substituted with radioactive iodotyrosyl (see Example 11). Any of the various isotopes of radioactive iodine can be incorporated to create a diagnostic agent. Preferably, ^{123}I (half-life = 13.2 hours) is used for whole body scintigraphy, ^{124}I (half life = 4 days) is used for positron emission tomography (PET), ^{125}I (half life = 60 days) is used for metabolic turnover studies and ^{131}I (half life = 8 days) is used for whole body counting and delayed low resolution imaging studies.

30

Furthermore, an additional modification of a modulator compound of the invention can serve to confer an additional therapeutic property on the compound. That is, the additional chemical modification can comprise an additional functional moiety. For example, a functional moiety which serves to break down or dissolve amyloid plaques can be coupled to the modulator compound. In this form, the MG-ACD portion of the modulator serves to target the compound to A β peptides and disrupt the polymerization of the A β peptides, whereas the additional functional moiety serves to break down or dissolve amyloid plaques after the compound has been targeted to these sites.

In an alternative chemical modification, a β -amyloid compound of the invention is prepared in a "prodrug" form, wherein the compound itself does not modulate A β aggregation, but rather is capable of being transformed, upon metabolism *in vivo*, into a β -amyloid modulator compound as defined herein. For example, in this type of compound, the modulating group can be present in a prodrug form that is capable of being converted upon metabolism into the form of an active modulating group. Such a prodrug form of a modifying group is referred to herein as a "secondary modifying group." A variety of strategies are known in the art for preparing peptide prodrugs that limit metabolism in order to optimize delivery of the active form of the peptide-based drug (see *e.g.*, Moss, J. (1995) in Peptide-Based Drug Design: Controlling Transport and Metabolism, Taylor, M.D. and Amidon, G.L. (eds), Chapter 18. Additionally strategies have been specifically tailored to achieving CNS delivery based on "sequential metabolism" (see *e.g.*, Bodor, N., *et al.* (1992) *Science* 257:1698-1700; Prokai, L., *et al.* (1994) *J. Am. Chem. Soc.* 116:2643-2644; Bodor, N. and Prokai, L. (1995) in Peptide-Based Drug Design: Controlling Transport and Metabolism, Taylor, M.D. and Amidon, G.L. (eds), Chapter 14. In one embodiment of a prodrug form of a modulator of the invention, the modifying group comprises an alkyl ester to facilitate blood-brain barrier permeability.

Modulator compounds of the invention can be prepared by standard techniques known in the art. The peptide component of a modulator composed, at least in part, of a peptide, can be synthesized using standard techniques such as those described in Bodansky, M. Principles of Peptide Synthesis, Springer Verlag, Berlin (1993) and Grant, G.A (ed.), Synthetic Peptides: A User's Guide, W.H. Freeman and Company, New York (1992). Automated peptide synthesizers are commercially available (*e.g.*, Advanced ChemTech Model 396; Milligen/ Biosearch 9600). Additionally, one or more modulating groups can be attached to the A β -derived peptidic component (*e.g.*, an A β aggregation core domain) by standard methods, for example using methods for reaction through an amino group (*e.g.*, the alpha-amino group at the amino-terminus of a peptide), a carboxyl group (*e.g.*, at the carboxy terminus of a peptide), a hydroxyl group (*e.g.*, on a tyrosine, serine or threonine residue) or other suitable reactive group on an amino acid side chain (see *e.g.*, Greene, T.W and Wuts, P.G.M. Protective Groups in Organic Synthesis, John Wiley and Sons, Inc., New York

(1991). Exemplary syntheses of preferred β amyloid modulators is described further in Examples 1, 4 and 11.

IV. Screening Assays

Another aspect of the invention pertains to a method for selecting a modulator of β -amyloid aggregation. In the method, a test compound is contacted with natural β amyloid peptides, the aggregation of the natural β -AP is measured and a modulator is selected based on the ability of the test compound to alter the aggregation of the natural β -AP (*e.g.*, inhibit or promote aggregation). In a preferred embodiment, the test compound is contacted with a molar excess amount of the natural β -AP. The amount and/or rate of natural β -AP aggregation in the presence of the test compound can be determined by a suitable assay indicative of β -AP aggregation, as described herein (see *e.g.*, Examples 2, 5 and 6).

In a preferred assay, the natural β -AP is dissolved in solution in the presence of the test compound and aggregation of the natural β -AP is assessed in a nucleation assay (see Example 6) by assessing the turbidity of the solution over time, as measured by the apparent absorbance of the solution at 405 nm (described further in Example 6; see also Jarrett *et al.* (1993) *Biochemistry* 32:4693-4697). In the absence of a β -amyloid modulator, the $A_{405\text{nm}}$ of the solution typically stays relatively constant during a lag time in which the β -AP remains in solution, but then the $A_{405\text{nm}}$ of the solution rapidly increases as the β -AP aggregates and comes out of solution, ultimately reaching a plateau level (*i.e.*, the $A_{405\text{nm}}$ of the solution exhibits sigmoidal kinetics over time). In contrast, in the presence of a test compound that inhibits β -AP aggregation, the $A_{405\text{nm}}$ of the solution is reduced compared to when the modulator is absent. Thus, in the presence of the inhibitory modulator, the solution may exhibit an increased lag time, a decreased slope of aggregation and/or a lower plateau level compared to when the modulator is absent. This method for selecting a modulator of β -amyloid polymerization can similarly be used to select modulators that promote β -AP aggregation. Thus, in the presence of a modulator that promotes β -AP aggregation, the $A_{405\text{nm}}$ of the solution is increased compared to when the modulator is absent (*e.g.*, the solution may exhibit an decreased lag time, increase slope of aggregation and/or a higher plateau level compared to when the modulator is absent).

Another assay suitable for use in the screening method of the invention, a seeded extension assay, is also described further in Example 6. In this assay, β -AP monomer and an aggregated β -AP "seed" are combined, in the presence and absence of a test compound, and the amount of β -fibril formation is assayed based on enhanced emission of the dye Thioflavine T when contacted with β -AP fibrils. Moreover, β -AP aggregation can be assessed by electron microscopy (EM) of the β -AP preparation in the presence or absence of the modulator. For example, β amyloid fibril formation, which is detectable by EM, is reduced in the presence of a modulator that inhibits β -AP aggregation (*i.e.*, there is a reduced amount or number of β -fibrils in the presence of the modulator), whereas β fibril formation is

increased in the presence of a modulator that promotes β -AP aggregation (*i.e.*, there is an increased amount or number of β -fibrils in the presence of the modulator).

An even more preferred assay for use in the screening method of the invention to select suitable modulators is the neurotoxicity assay described in Examples 3 and 10.

- 5 Compounds are selected which inhibit the formation of neurotoxic A β aggregates and/or which inhibit the neurotoxicity of preformed A β fibrils. This neurotoxicity assay is considered to be predictive of neurotoxicity *in vivo*. Accordingly, inhibitory activity of a modulator compound in the *in vitro* neurotoxicity assay is predictive of similar inhibitory activity of the compound for neurotoxicity *in vivo*.

10

V. Pharmaceutical Compositions

- Another aspect of the invention pertains to pharmaceutical compositions of the β -amyloid modulator compounds of the invention. In one embodiment, the composition includes a β amyloid modulator compound in a therapeutically or prophylactically effective amount sufficient to alter, and preferably inhibit, aggregation of natural β -amyloid peptides, and a pharmaceutically acceptable carrier. In another embodiment, the composition includes a β amyloid modulator compound in a therapeutically or prophylactically effective amount sufficient to inhibit the neurotoxicity of natural β -amyloid peptides, and a pharmaceutically acceptable carrier. A "therapeutically effective amount" refers to an amount effective, at dosages and for periods of time necessary, to achieve the desired therapeutic result, such as reduction or reversal of β -amyloid deposition and/or reduction or reversal of A β neurotoxicity. A therapeutically effective amount of modulator may vary according to factors such as the disease state, age, sex, and weight of the individual, and the ability of the modulator to elicit a desired response in the individual. Dosage regimens may be adjusted to provide the optimum therapeutic response. A therapeutically effective amount is also one in which any toxic or detrimental effects of the modulator are outweighed by the therapeutically beneficial effects. The potential neurotoxicity of the modulators of the invention can be assayed using the cell-based assay described in Examples 3 and 10 and a therapeutically effective modulator can be selected which does not exhibit significant neurotoxicity. In a preferred embodiment, a therapeutically effective amount of a modulator is sufficient to alter, and preferably inhibit, aggregation of a molar excess amount of natural β -amyloid peptides. A "prophylactically effective amount" refers to an amount effective, at dosages and for periods of time necessary, to achieve the desired prophylactic result, such as preventing or inhibiting the rate of β -amyloid deposition and/or A β neurotoxicity in a subject predisposed to β -amyloid deposition. A prophylactically effective amount can be determined as described above for the therapeutically effective amount. Typically, since a prophylactic dose is used in subjects prior to or at an earlier stage of disease, the prophylactically effective amount will be less than the therapeutically effective amount.

One factor that may be considered when determining a therapeutically or prophylactically effective amount of a β amyloid modulator is the concentration of natural β -AP in a biological compartment of a subject, such as in the cerebrospinal fluid (CSF) of the subject. The concentration of natural β -AP in the CSF has been estimated at 3 nM

(Schwartzman, (1994) *Proc. Natl. Acad. Sci. USA* 91:8368-8372). A non-limiting range for a therapeutically or prophylactically effective amounts of a β amyloid modulator is 0.01 nM-10 μ M. It is to be noted that dosage values may vary with the severity of the condition to be alleviated. It is to be further understood that for any particular subject, specific dosage regimens should be adjusted over time according to the individual need and the professional judgment of the person administering or supervising the administration of the compositions, and that dosage ranges set forth herein are exemplary only and are not intended to limit the scope or practice of the claimed composition.

The amount of active compound in the composition may vary according to factors such as the disease state, age, sex, and weight of the individual, each of which may affect the amount of natural β -AP in the individual. Dosage regimens may be adjusted to provide the optimum therapeutic response. For example, a single bolus may be administered, several divided doses may be administered over time or the dose may be proportionally reduced or increased as indicated by the exigencies of the therapeutic situation. It is especially advantageous to formulate parenteral compositions in dosage unit form for ease of administration and uniformity of dosage. Dosage unit form as used herein refers to physically discrete units suited as unitary dosages for the mammalian subjects to be treated; each unit containing a predetermined quantity of active compound calculated to produce the desired therapeutic effect in association with the required pharmaceutical carrier. The specification for the dosage unit forms of the invention are dictated by and directly dependent on (a) the unique characteristics of the active compound and the particular therapeutic effect to be achieved, and (b) the limitations inherent in the art of compounding such an active compound for the treatment of sensitivity in individuals.

As used herein "pharmaceutically acceptable carrier" includes any and all solvents, dispersion media, coatings, antibacterial and antifungal agents, isotonic and absorption delaying agents, and the like that are physiologically compatible. In one embodiment, the carrier is suitable for parenteral administration. Preferably, the carrier is suitable for administration into the central nervous system (*e.g.*, intraspinally or intracerebrally). Alternatively, the carrier can be suitable for intravenous, intraperitoneal or intramuscular administration. In another embodiment, the carrier is suitable for oral administration.

Pharmaceutically acceptable carriers include sterile aqueous solutions or dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersion. The use of such media and agents for pharmaceutically active substances is well known in the art. Except insofar as any conventional media or agent is incompatible with the active compound, use thereof in the pharmaceutical compositions of the invention is

34

contemplated. Supplementary active compounds can also be incorporated into the compositions.

Therapeutic compositions typically must be sterile and stable under the conditions of manufacture and storage. The composition can be formulated as a solution, microemulsion, liposome, or other ordered structure suitable to high drug concentration. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (for example, glycerol, propylene glycol, and liquid polyethylene glycol, and the like), and suitable mixtures thereof. The proper fluidity can be maintained, for example, by the use of a coating such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. In many cases, it will be preferable to include isotonic agents, for example, sugars, polyalcohols such as manitol, sorbitol, or sodium chloride in the composition. Prolonged absorption of the injectable compositions can be brought about by including in the composition an agent which delays absorption, for example, monostearate salts and gelatin. Moreover, the modulators can be administered in a time release formulation, for example in a composition which includes a slow release polymer. The active compounds can be prepared with carriers that will protect the compound against rapid release, such as a controlled release formulation, including implants and microencapsulated delivery systems. Biodegradable, biocompatible polymers can be used, such as ethylene vinyl acetate, polyanhydrides, polyglycolic acid, collagen, polyorthoesters, polylactic acid and polylactic, polyglycolic copolymers (PLG). Many methods for the preparation of such formulations are patented or generally known to those skilled in the art.

Sterile injectable solutions can be prepared by incorporating the active compound (e.g., β -amyloid modulator) in the required amount in an appropriate solvent with one or a combination of ingredients enumerated above, as required, followed by filtered sterilization. Generally, dispersions are prepared by incorporating the active compound into a sterile vehicle which contains a basic dispersion medium and the required other ingredients from those enumerated above. In the case of sterile powders for the preparation of sterile injectable solutions, the preferred methods of preparation are vacuum drying and freeze-drying which yields a powder of the active ingredient plus any additional desired ingredient from a previously sterile-filtered solution thereof.

A modulator compound of the invention can be formulated with one or more additional compounds that enhance the solubility of the modulator compound. Preferred compounds to be added to formulations to enhance the solubility of the modulators are cyclodextrin derivatives, preferably hydroxypropyl- γ -cyclodextrin. Drug delivery vehicles containing a cyclodextrin derivative for delivery of peptides to the central nervous system are described in Bodor, N., *et al.* (1992) *Science* 257:1698-1700. For the β -amyloid modulators described herein, inclusion in the formulation of hydroxypropyl- γ -cyclodextrin at a concentration 50-200 mM increases the aqueous solubility of the compounds. In addition to increased solubility, inclusion of a cyclodextrin derivative in the formulation may have other

beneficial effects, since β -cyclodextrin itself has been reported to interact with the A β peptide and inhibit fibril formation *in vitro* (Camilleri, P., *et al.* (1994) *FEBS Letters* 341:256-258.

Accordingly, use of a modulator compound of the invention in combination with a cyclodextrin derivative may result in greater inhibition of A β aggregation than use of the modulator alone. Chemical modifications of cyclodextrins are known in the art (Hanessian, S., *et al.* (1995) *J. Org. Chem.* 60:4786-4797). In addition to use as an additive in a pharmaceutical composition containing a modulator of the invention, cyclodextrin derivatives may also be useful as modifying groups and, accordingly, may also be covalently coupled to an A β peptide compound to form a modulator compound of the invention.

In another embodiment, a pharmaceutical composition comprising a modulator of the invention is formulated such that the modulator is transported across the blood-brain barrier (BBB). Various strategies known in the art for increasing transport across the BBB can be adapted to the modulators of the invention to thereby enhance transport of the modulators across the BBB (for reviews of such strategies, see *e.g.*, Pardridge, W.M. (1994) *Trends in Biotechnol.* 12:239-245; Van Bree, J.B. *et al.* (1993) *Pharm. World Sci.* 15:2-9; and Pardridge, W.M. *et al.* (1992) *Pharmacol. Toxicol.* 71:3-10). In one approach, the modulator is chemically modified to form a prodrug with enhanced transmembrane transport. Suitable chemical modifications include covalent linking of a fatty acid to the modulator through an amide or ester linkage (see *e.g.*, U.S. Patent 4,933,324 and PCT Publication WO 89/07938, both by Shashoua; U.S. Patent 5,284,876 by Hesse *et al.*; Toth, I. *et al.* (1994) *J. Drug Target.* 2:217-239; and Shashoua, V.E. *et al.* (1984) *J. Med. Chem.* 27:659-664) and glycosylating the modulator (see *e.g.*, U.S. Patent 5,260,308 by Poduslo *et al.*). Also, N-acetylamino acid derivatives may be used in a modulator to form a "lipidic" prodrug (see *e.g.*, 5,112,863 by Hashimoto *et al.*).

In another approach for enhancing transport across the BBB, a peptidic or peptidomimetic modulator is conjugated to a second peptide or protein, thereby forming a chimeric protein, wherein the second peptide or protein undergoes absorptive-mediated or receptor-mediated transcytosis through the BBB. Accordingly, by coupling the modulator to this second peptide or protein, the chimeric protein is transported across the BBB. The second peptide or protein can be a ligand for a brain capillary endothelial cell receptor ligand. For example, a preferred ligand is a monoclonal antibody that specifically binds to the transferrin receptor on brain capillary endothelial cells (see *e.g.*, U.S. Patents 5,182,107 and 5,154,924 and PCT Publications WO 93/10819 and WO 95/02421, all by Friden *et al.*). Other suitable peptides or proteins that can mediate transport across the BBB include histones (see *e.g.*, U.S. Patent 4,902,505 by Pardridge and Schimmel) and ligands such as biotin, folate, niacin, pantothenic acid, riboflavin, thiamin, pyridoxal and ascorbic acid (see *e.g.*, U.S. Patents 5,416,016 and 5,108,921, both by Heinsteins). Additionally, the glucose transporter GLUT-1 has been reported to transport glycopeptides (L-serinyl- β -D-glucoside analogues of [Met⁵]enkephalin) across the BBB (Polt, R. *et al.* (1994) *Proc. Natl. Acad. Sci.*

36

USA 91:7114-1778). Accordingly, a modulator compound can be coupled to such a glycopeptide to target the modulator to the GLUT-1 glucose transporter. For example, a modulator compound which is modified at its amino terminus with the modifying group Aic (3-(*O*-aminoethyl-*iso*)-choly), a derivative of cholic acid having a free amino group) can be coupled to a glycopeptide through the amino group of Aic by standard methods. Chimeric proteins can be formed by recombinant DNA methods (*e.g.*, by formation of a chimeric gene encoding a fusion protein) or by chemical crosslinking of the modulator to the second peptide or protein to form a chimeric protein. Numerous chemical crosslinking agents are known in the (*e.g.*, commercially available from Pierce, Rockford IL). A crosslinking agent can be chosen which allows for high yield coupling of the modulator to the second peptide or protein and for subsequent cleavage of the linker to release bioactive modulator. For example, a biotin-avidin-based linker system may be used.

In yet another approach for enhancing transport across the BBB, the modulator is encapsulated in a carrier vector which mediates transport across the BBB. For example, the modulator can be encapsulated in a liposome, such as a positively charged unilamellar liposome (see *e.g.*, PCT Publications WO 88/07851 and WO 88/07852, both by Faden) or in polymeric microspheres (see *e.g.*, U.S. Patent 5,413,797 by Khan *et al.*, U.S. Patent 5,271,961 by Mathiowitz *et al.* and 5,019,400 by Gombotz *et al.*). Moreover, the carrier vector can be modified to target it for transport across the BBB. For example, the carrier vector (*e.g.*, liposome) can be covalently modified with a molecule which is actively transported across the BBB or with a ligand for brain endothelial cell receptors, such as a monoclonal antibody that specifically binds to transferrin receptors (see *e.g.*, PCT Publications WO 91/04014 by Collins *et al.* and WO 94/02178 by Greig *et al.*).

In still another approach to enhancing transport of the modulator across the BBB, the modulator is coadministered with another agent which functions to permeabilize the BBB. Examples of such BBB "permeabilizers" include bradykinin and bradykinin agonists (see *e.g.*, U.S. Patent 5,112,596 by Malfroy-Camine) and peptidic compounds disclosed in U.S. Patent 5,268,164 by Kozarich *et al.*

A modulator compound of the invention can be formulated into a pharmaceutical composition wherein the modulator is the only active compound or, alternatively, the pharmaceutical composition can contain additional active compounds. For example, two or more modulator compounds may be used in combination. Moreover, a modulator compound of the invention can be combined with one or more other agents that have anti-amyloidogenic properties. For example, a modulator compound can be combined with the non-specific cholinesterase inhibitor tacrine (Cognex®, Parke-Davis).

In another embodiment, a pharmaceutical composition of the invention is provided as a packaged formulation. The packaged formulation may include a pharmaceutical composition of the invention in a container and printed instructions for administration of the

composition for treating a subject having a disorder associated with β -amyloidosis, *e.g.* Alzheimer's disease.

VI. Methods of Using A β Modulators

5 Another aspect of the invention pertains to methods for altering the aggregation or inhibiting the neurotoxicity of natural β -amyloid peptides. In the methods of the invention, natural β amyloid peptides are contacted with a β amyloid modulator such that the aggregation of the natural β amyloid peptides is altered or the neurotoxicity of the natural β amyloid peptides is inhibited. In a preferred embodiment, the modulator inhibits aggregation
10 of the natural β amyloid peptides. In another embodiment, the modulator promotes aggregation of the natural β amyloid peptides. Preferably, aggregation of a molar excess amount of β -AP, relative to the amount of modulator, is altered upon contact with the modulator.

In the method of the invention, natural β amyloid peptides can be contacted with a
15 modulator either *in vitro* or *in vivo*. Thus, the term "contacted with" is intended to encompass both incubation of a modulator with a natural β -AP preparation *in vitro* and delivery of the modulator to a site *in vivo* where natural β -AP is present. Since the modulator compound interacts with natural β -AP, the modulator compounds can be used to detect natural β -AP, either *in vitro* or *in vivo*. Accordingly, one use of the modulator compounds of the invention
20 is as diagnostic agents to detect the presence of natural β -AP, either in a biological sample or *in vivo* in a subject. Furthermore, detection of natural β -AP utilizing a modulator compound of the invention further can be used to diagnose amyloidosis in a subject. Additionally, since the modulator compounds of the invention disrupt β -AP aggregation and inhibit β -AP neurotoxicity, the modulator compounds also are useful in the treatment of disorders
25 associated with β -amyloidosis, either prophylactically or therapeutically. Accordingly, another use of the modulator compounds of the invention is as therapeutic agents to alter aggregation and/or neurotoxicity of natural β -AP.

In one embodiment, a modulator compound of the invention is used *in vitro*, for example to detect and quantitate natural β -AP in sample (*e.g.*, a sample of biological fluid).

30 To aid in detection, the modulator compound can be modified with a detectable substance.

The source of natural β -AP used in the method can be, for example, a sample of cerebrospinal fluid (*e.g.*, from an AD patient, an adult susceptible to AD due to family history, or a normal adult). The natural β -AP sample is contacted with a modulator of the invention and aggregation of the β -AP is measured, such as by as assay described in

35 Examples 2, 5 and 6. Preferably, the nucleation assay and/or seeded extension assay described in Example 6 is used. The degree of aggregation of the β -AP sample can then be compared to that of a control sample(s) of a known concentration of β -AP, similarly contacted with the modulator and the results can be used as an indication of whether a subject is susceptible to or has a disorder associated with β -amyloidosis. Moreover, β -AP can be

detected by detecting a modulating group incorporated into the modulator. For example, modulators incorporating a biotin compound as described herein (*e.g.*, an amino-terminally biotinylated β -AP peptide) can be detected using a streptavidin or avidin probe which is labeled with a detectable substance (*e.g.*, an enzyme, such as peroxidase). Detection of natural β -AP aggregates mixed with a modulator of the invention using a probe that binds to the modulating group (*e.g.*, biotin/streptavidin) is described further in Example 2.

In another embodiment, a modulator compound of the invention is used *in vivo* to detect, and, if desired, quantitate, natural β -AP deposition in a subject, for example to aid in the diagnosis of β amyloidosis in the subject. To aid in detection, the modulator compound can be modified with a detectable substance, preferably ^{99m}Tc or radioactive iodine (described further above), which can be detected *in vivo* in a subject. The labeled β -amyloid modulator compound is administered to the subject and, after sufficient time to allow accumulation of the modulator at sites of amyloid deposition, the labeled modulator compound is detected by standard imaging techniques. The radioactive signal generated by the labeled compound can be directly detected (*e.g.*, whole body counting), or alternatively, the radioactive signal can be converted into an image on an autoradiograph or on a computer screen to allow for imaging of amyloid deposits in the subject. Methods for imaging amyloidosis using radiolabeled proteins are known in the art. For example, serum amyloid P component (SAP), radiolabeled with either ^{123}I or ^{99m}Tc , has been used to image systemic amyloidosis (see *e.g.*, Hawkins, P.N. and Pepys, M.B. (1995) *Eur. J. Nucl. Med.* 22:595-599). Of the various isotopes of radioactive iodine, preferably ^{123}I (half-life = 13.2 hours) is used for whole body scintigraphy, ^{124}I (half life = 4 days) is used for positron emission tomography (PET). ^{125}I (half life = 60 days) is used for metabolic turnover studies and ^{131}I (half life = 8 days) is used for whole body counting and delayed low resolution imaging studies. Analogous to studies using radiolabeled SAP, a labeled modulator compound of the invention can be delivered to a subject by an appropriate route (*e.g.*, intravenously, intraspinally, intracerebrally) in a single bolus, for example containing 100 μg of labeled compound carrying approximately 180 MBq of radioactivity.

The invention provides a method for detecting the presence or absence of natural β -amyloid peptides in a biological sample, comprising contacting a biological sample with a compound of the invention and detecting the compound bound to natural β -amyloid peptides to thereby detect the presence or absence of natural β -amyloid peptides in the biological sample. In one embodiment, the β -amyloid modulator compound and the biological sample are contacted *in vitro*. In another embodiment, the β -amyloid modulator compound is contacted with the biological sample by administering the β -amyloid modulator compound to a subject. For *in vivo* administration, preferably the compound is labeled with radioactive technetium or radioactive iodine.

The invention also provides a method for detecting natural β -amyloid peptides to facilitate diagnosis of a β -amyloidogenic disease, comprising contacting a biological sample

with the compound of the invention and detecting the compound bound to natural β -amyloid peptides to facilitate diagnosis of a β -amyloidogenic disease. In one embodiment, the β -amyloid modulator compound and the biological sample are contacted *in vitro*. In another embodiment, the β -amyloid modulator compound is contacted with the biological sample by administering the β -amyloid modulator compound to a subject. For *in vivo* administration, preferably the compound is labeled with radioactive technetium or radioactive iodine. Preferably, use of the method facilitates diagnosis of Alzheimer's disease.

In another embodiment, the invention provides a method for altering natural β -AP aggregation or inhibiting β -AP neurotoxicity, which can be used prophylactically or therapeutically in the treatment or prevention of disorders associated with β amyloidosis, *e.g.*, Alzheimer's Disease. As demonstrated in Example 10, modulator compounds of the invention reduce the toxicity of natural β -AP aggregates to cultured neuronal cells. Moreover, the modulators not only reduce the formation of neurotoxic aggregates but also have the ability to reduce the neurotoxicity of preformed A β fibrils. Accordingly, the modulator compounds of the invention can be used to inhibit or prevent the formation of neurotoxic A β fibrils in subjects (*e.g.*, prophylactically in a subject predisposed to β -amyloid deposition) and can be used to reverse β -amyloidosis therapeutically in subjects already exhibiting β -amyloid deposition.

A modulator of the invention is contacted with natural β amyloid peptides present in a subject (*e.g.*, in the cerebrospinal fluid or cerebrum of the subject) to thereby alter the aggregation of the natural β -AP and/or inhibit the neurotoxicity of the natural β -APs. A modulator compound alone can be administered to the subject, or alternatively, the modulator compound can be administered in combination with other therapeutically active agents (*e.g.*, as discussed above in subsection IV). When combination therapy is employed, the therapeutic agents can be coadministered in a single pharmaceutical composition, coadministered in separate pharmaceutical compositions or administered sequentially.

The modulator may be administered to a subject by any suitable route effective for inhibiting natural β -AP aggregation in the subject, although in a particularly preferred embodiment, the modulator is administered parenterally, most preferably to the central nervous system of the subject. Possible routes of CNS administration include intraspinal administration and intracerebral administration (*e.g.*, intracerebrovascular administration). Alternatively, the compound can be administered, for example, orally, intraperitoneally, intravenously or intramuscularly. For non-CNS administration routes, the compound can be administered in a formulation which allows for transport across the BBB. Certain modulators may be transported across the BBB without any additional further modification whereas others may need further modification as described above in subsection IV.

Suitable modes and devices for delivery of therapeutic compounds to the CNS of a subject are known in the art, including cerebrovascular reservoirs (*e.g.*, Ommaya or Rikker reservoirs; see *e.g.*, Raney, J.P. *et al.* (1988) *J. Neurosci. Nurs.* 20:23-29; Sundaresan, N. *et*

al. (1989) *Oncology* 3:15-22), catheters for intrathecal delivery (*e.g.*, Port-a-Cath, Y-catheters and the like; see *e.g.*, Plummer, J.L. (1991) *Pain* 44:215-220; Yaksh, T.L. *et al.* (1986) *Pharmacol. Biochem. Behav.* 25:483-485), injectable intrathecal reservoirs (*e.g.*, Spinalgesic; see *e.g.*, Brazenor, G.A. (1987) *Neurosurgery* 21:484-491), implantable infusion pump systems (*e.g.*, Infusaid; see *e.g.*, Zierski, J. *et al.* (1988) *Acta Neurochem. Suppl.* 43:94-99; Kanoff, R.B. (1994) *J. Am. Osteopath. Assoc.* 94:487-493) and osmotic pumps (sold by Alza Corporation). A particularly preferred mode of administration is via an implantable, externally programmable infusion pump. Suitable infusion pump systems and reservoir systems are also described in U.S. Patent No. 5, 368,562 by Blomquist and U.S. Patent No. 4,731,058 by Doan, developed by Pharmacia Deltec Inc.

The method of the invention for altering β -AP aggregation *in vivo*, and in particular for inhibiting β -AP aggregation, can be used therapeutically in diseases associated with abnormal β amyloid aggregation and deposition to thereby slow the rate of β amyloid deposition and/or lessen the degree of β amyloid deposition, thereby ameliorating the course of the disease. In a preferred embodiment, the method is used to treat Alzheimer's disease (*e.g.*, sporadic or familial AD, including both individuals exhibiting symptoms of AD and individuals susceptible to familial AD). The method can also be used prophylactically or therapeutically to treat other clinical occurrences of β amyloid deposition, such as in Down's syndrome individuals and in patients with hereditary cerebral hemorrhage with amyloidosis-Dutch-type (HCHWA-D). While inhibition of β -AP aggregation is a preferred therapeutic method, modulators that promote β -AP aggregation may also be useful therapeutically by allowing for the sequestration of β -AP at sites that do not lead to neurological impairment.

Additionally, abnormal accumulation of β -amyloid precursor protein in muscle fibers has been implicated in the pathology of sporadic inclusion body myositis (IBM) (Askana, V. *et al.* (1996) *Proc. Natl. Acad. Sci. USA* 93:1314-1319; Askanas, V. *et al.* (1995) *Current Opinion in Rheumatology* 7:486-496). Accordingly, the modulators of the invention can be used prophylactically or therapeutically in the treatment of disorders in which β -AP, or APP, is abnormally deposited at non-neurological locations, such as treatment of IBM by delivery of the modulators to muscle fibers.

VII. Unmodified A β Peptides that Inhibit Aggregation of Natural β -AP

In addition to the β -amyloid modulators described hereinbefore in which an A β peptide is coupled to a modifying group, the invention also provides β -amyloid modulators comprised of an unmodified A β peptide. It has now been discovered that certain portions of natural β -AP can alter aggregation of natural β -APs when contacted with the natural β -APs (see Example 12). Accordingly, these unmodified A β peptides comprise a portion of the natural β -AP sequence (*i.e.*, a portion of β AP₁₋₃₉, β AP₁₋₄₀, β AP₁₋₄₂ and β AP₁₋₄₃). In particular these unmodified A β peptides have at least one amino acid deletion compared to β AP₁₋₃₉, the shortest natural β -AP, such that the compound alters aggregation of natural β -

amyloid peptides when contacted with the natural β -amyloid peptides. In various embodiments, these unmodified peptide compounds can promote aggregation of natural β -amyloid peptides, or, more preferably, can inhibit aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. Even more preferably, the unmodified peptide compound inhibits aggregation of natural β -amyloid peptides when contacted with a molar excess amount of natural β -amyloid peptides (*e.g.*, a 10-fold, 33-fold or 100-fold molar excess amount of natural β -AP).

As discussed above, the unmodified peptide compounds of the invention comprise an amino acid sequence having at least one amino acid deletion compared to the amino acid sequence of β AP₁₋₃₉. Alternatively, the unmodified peptide compound can have at least five, ten, fifteen, twenty, twenty-five, thirty or thirty-five amino acids deleted compared to β AP₁₋₃₉. Still further the unmodified peptide compound can have 1-5, 1-10, 1-15, 1-20, 1-25, 1-30 or 1-35 amino acids deleted compared to β AP₁₋₃₉. The amino acid deletion(s) may occur at the amino-terminus, the carboxy-terminus, an internal site, or a combination thereof of the β -AP sequence. Accordingly, in one embodiment, an unmodified peptide compound of the invention comprises an amino acid sequence which has at least one internal amino acid deleted compared to β AP₁₋₃₉. Alternatively, the unmodified peptide compound can have at least five, ten, fifteen, twenty, twenty-five, thirty or thirty-five internal amino acids deleted compared to β AP₁₋₃₉. Still further the unmodified peptide compound can have 1-5, 1-10, 1-15, 1-20, 1-25, 1-30 or 1-35 internal amino acids deleted compared to β AP₁₋₃₉. For peptides with internal deletions, preferably the peptide has an amino terminus corresponding to amino acid residue 1 of natural β AP and a carboxy terminus corresponding to residue 40 of natural β AP and has one or more internal β -AP amino acid residues deleted (*i.e.*, a non-contiguous A β peptide).

In another embodiment, the unmodified peptide compound comprises an amino acid sequence which has at least one N-terminal amino acid deleted compared to β AP₁₋₃₉. Alternatively, the unmodified peptide compound can have at least five, ten, fifteen, twenty, twenty-five, thirty or thirty-five N-terminal amino acids deleted compared to β AP₁₋₃₉. Still further the unmodified peptide compound can have 1-5, 1-10, 1-15, 1-20, 1-25, 1-30 or 1-35 N-terminal amino acids deleted compared to β AP₁₋₃₉.

In yet another embodiment, the unmodified peptide compound comprises an amino acid sequence which has at least one C-terminal amino acid deleted compared to β AP₁₋₃₉. Alternatively, the unmodified peptide compound can have at least five, ten, fifteen, twenty, twenty-five, thirty or thirty-five C-terminal amino acids deleted compared to β AP₁₋₃₉. Still further the unmodified peptide compound can have 1-5, 1-10, 1-15, 1-20, 1-25, 1-30 or 1-35 C-terminal amino acids deleted compared to β AP₁₋₃₉.

In addition to deletion of amino acids as compared to β AP₁₋₃₉, the peptide compound can have additional non- β -AP amino acid residues added to it, for example, at the amino terminus, the carboxy-terminus or at an internal site. In one embodiment, the peptide

compound has at least one non- β -amyloid peptide-derived amino acid at its N-terminus.

Alternatively, the compound can have, for example, 1-3, 1-5, 1-7, 1-10, 1-15 or 1-20 non- β -amyloid peptide-derived amino acid at its N-terminus. In another embodiment, the peptide compound has at least one non- β -amyloid peptide-derived amino acid at its C-terminus.

- 5 Alternatively, the compound can have, for example, 1-3, 1-5, 1-7, 1-10, 1-15 or 1-20 non- β -amyloid peptide-derived amino acid at its C-terminus.

In specific preferred embodiments, an unmodified peptide compound of the invention comprises $A\beta_{6-20}$ (the amino acid sequence of which is shown in SEQ ID NO: 4), $A\beta_{16-30}$ (the amino acid sequence of which is shown in SEQ ID NO: 14), $A\beta_{1-20, 26-40}$ (the amino acid sequence of which is shown in SEQ ID NO: 15) or $EEVVHHHHQQ-\beta AP_{16-40}$ (the amino acid sequence of which is shown in SEQ ID NO: 16). In the nomenclature used
10 herein, $\beta AP_{1-20, 26-40}$ represents βAP_{1-40} in which the internal amino acid residues 21-25 have been deleted.

An unmodified peptide compound of the invention can be chemically synthesized
15 using standard techniques such as those described in Bodansky, M. *Principles of Peptide Synthesis*. Springer Verlag, Berlin (1993) and Grant, G.A (ed.). *Synthetic Peptides: A User's Guide*, W.H. Freeman and Company, New York (1992). Automated peptide synthesizers are commercially available (e.g., Advanced ChemTech Model 396; Milligen/ Biosearch 9600). Alternatively, unmodified peptide compounds can be prepared according to standard
20 recombinant DNA techniques using a nucleic acid molecule encoding the peptide. A nucleotide sequence encoding the peptide can be determined using the genetic code and an oligonucleotide molecule having this nucleotide sequence can be synthesized by standard DNA synthesis methods (e.g., using an automated DNA synthesizer). Alternatively, a DNA molecule encoding an unmodified peptide compound can be derived from the natural β -
25 amyloid precursor protein gene or cDNA (e.g., using the polymerase chain reaction and/or restriction enzyme digestion) according to standard molecular biology techniques.

Accordingly, the invention further provides an isolated nucleic acid molecule comprising a nucleotide sequence encoding a β -amyloid peptide compound, the β -amyloid peptide compound comprising an amino acid sequence having at least one amino acid
30 deletion compared to βAP_{1-39} such that the β -amyloid peptide compound alters aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides. As used herein, the term "nucleic acid molecule" is intended to include DNA molecules and RNA molecules and may be single-stranded or double-stranded, but preferably is double-stranded DNA. The isolated nucleic acid encodes a peptide wherein one or more amino acids are
35 deleted from the N-terminus, C-terminus and/or an internal site of βAP_{1-39} , as discussed above. In yet other embodiments, the isolated nucleic acid encodes a peptide compound having one or more amino acids deleted compared to βAP_{1-39} and further having at least one non- β -AP derived amino acid residue added to it. for example, at the amino terminus, the carboxy-terminus or at an internal site. In specific preferred embodiments, an isolated

nucleic acid molecule of the invention encodes β AP₆₋₂₀, β AP₁₆₋₃₀, β AP_{1-20, 26-40} or EEVVHHHHQQ- β AP₁₆₋₄₀.

To facilitate expression of a peptide compound in a host cell by standard recombinant DNA techniques, the isolated nucleic acid encoding the peptide is incorporated into a recombinant expression vector. Accordingly, the invention also provides recombinant expression vectors comprising the nucleic acid molecules of the invention. As used herein, the term "vector" refers to a nucleic acid molecule capable of transporting another nucleic acid to which it has been linked. One type of vector is a "plasmid", which refers to a circular double stranded DNA loop into which additional DNA segments may be ligated. Another type of vector is a viral vector, wherein additional DNA segments may be ligated into the viral genome. Certain vectors are capable of autonomous replication in a host cell into which they are introduced (*e.g.*, bacterial vectors having a bacterial origin of replication and episomal mammalian vectors). Other vectors (*e.g.*, non-episomal mammalian vectors) are integrated into the genome of a host cell upon introduction into the host cell, and thereby are replicated along with the host genome. Moreover, certain vectors are capable of directing the expression of genes to which they are operatively linked. Such vectors are referred to herein as "recombinant expression vectors" or simply "expression vectors". In general, expression vectors of utility in recombinant DNA techniques are often in the form of plasmids. In the present specification, "plasmid" and "vector" may be used interchangeably as the plasmid is the most commonly used form of vector. However, the invention is intended to include such other forms of expression vectors, such as viral vectors, which serve equivalent functions.

In the recombinant expression vectors of the invention, the nucleotide sequence encoding the peptide compound are operatively linked to one or more regulatory sequences selected on the basis of the host cells to be used for expression. The term "operably linked" is intended to mean that the sequences encoding the peptide compound are linked to the regulatory sequence(s) in a manner that allows for expression of the peptide compound. The term "regulatory sequence" is intended to include promoters, enhancers and other expression control elements (*e.g.*, polyadenylation signals). Such regulatory sequences are described, for example, in Goeddel; *Gene Expression Technology: Methods in Enzymology* 185, Academic Press, San Diego, CA (1990). Regulatory sequences include those that direct constitutive expression of a nucleotide sequence in many types of host cell, those that direct expression of the nucleotide sequence only in certain host cells (*e.g.*, tissue-specific regulatory sequences) and those that direct expression in a regulatable manner (*e.g.*, only in the presence of an inducing agent). It will be appreciated by those skilled in the art that the design of the expression vector may depend on such factors as the choice of the host cell to be transformed, the level of expression of peptide compound desired, *etc.* The expression vectors of the invention can be introduced into host cells thereby to produce peptide compounds encoded by nucleic acids as described herein.

The recombinant expression vectors of the invention can be designed for expression of peptide compounds in prokaryotic or eukaryotic cells. For example, peptide compounds can be expressed in bacterial cells such as *E. coli*, insect cells (using baculovirus expression vectors) yeast cells or mammalian cells. Suitable host cells are discussed further in Goeddel, 5 *Gene Expression Technology: Methods in Enzymology* 185, Academic Press, San Diego, CA (1990). Alternatively, the recombinant expression vector may be transcribed and translated *in vitro*, for example using T7 promoter regulatory sequences and T7 polymerase. Examples of vectors for expression in yeast *S. cerevisiae* include pYepSec1 (Baldari *et al.*, (1987) *EMBO J.* 6:229-234), pMFa (Kurjan and Herskowitz, (1982) *Cell* 30:933-943), pJRY88 10 (Schultz *et al.*, (1987) *Gene* 54:113-123), and pYES2 (Invitrogen Corporation, San Diego, CA). Baculovirus vectors available for expression of proteins or peptides in cultured insect cells (*e.g.*, Sf 9 cells) include the pAc series (Smith *et al.*, (1983) *Mol. Cell. Biol.* 3:2156-2165) and the pVL series (Lucklow, V.A., and Summers, M.D., (1989) *Virology* 170:31-39). Examples of mammalian expression vectors include pCDM8 (Seed, B., (1987) *Nature* 15 329:840) and pMT2PC (Kaufman *et al.* (1987). *EMBO J.* 6:187-195). When used in mammalian cells, the expression vector's control functions are often provided by viral regulatory elements. For example, commonly used promoters are derived from polyoma, Adenovirus 2, cytomegalovirus and Simian Virus 40.

In addition to the regulatory control sequences discussed above, the recombinant 20 expression vector may contain additional nucleotide sequences. For example, the recombinant expression vector may encode a selectable marker gene to identify host cells that have incorporated the vector. Such selectable marker genes are well known in the art. Moreover, the facilitate secretion of the peptide compound from a host cell, in particular mammalian host cells, the recombinant expression vector preferably encodes a signal 25 sequence operatively linked to sequences encoding the amino-terminus of the peptide compound such that upon expression, the peptide compound is synthesized with the signal sequence fused to its amino terminus. This signal sequence directs the peptide compound into the secretory pathway of the cell and is then cleaved, allowing for release of the mature peptide compound (*i.e.*, the peptide compound without the signal sequence) from 30 the host cell. Use of a signal sequence to facilitate secretion of proteins or peptides from mammalian host cells is well known in the art.

A recombinant expression vector comprising a nucleic acid encoding a peptide compound that alters aggregation of natural β -AP can be introduced into a host cell to thereby produce the peptide compound in the host cell. Accordingly, the invention also 35 provides host cells containing the recombinant expression vectors of the invention. The terms "host cell" and "recombinant host cell" are used interchangeably herein. It is understood that such terms refer not only to the particular subject cell but to the progeny or potential progeny of such a cell. Because certain modifications may occur in succeeding generations due to either mutation or environmental influences, such progeny may not, in

fact, be identical to the parent cell, but are still included within the scope of the term as used herein. A host cell may be any prokaryotic or eukaryotic cell. For example, a peptide compound may be expressed in bacterial cells such as *E. coli*, insect cells, yeast or mammalian cells. Preferably, the peptide compound is expressed in mammalian cells. In a
5 preferred embodiment, the peptide compound is expressed in mammalian cells *in vivo* in a mammalian subject to treat amyloidosis in the subject through gene therapy (discussed further below). Preferably, the β -amyloid peptide compound encoded by the recombinant expression vector is secreted from the host cell upon being expressed in the host cell.

Vector DNA can be introduced into prokaryotic or eukaryotic cells *via* conventional
10 transformation or transfection techniques. As used herein, the terms "transformation" and "transfection" are intended to refer to a variety of art-recognized techniques for introducing foreign nucleic acid (*e.g.*, DNA) into a host cell, including calcium phosphate or calcium chloride co-precipitation, DEAE-dextran-mediated transfection, lipofection, electroporation, microinjection and viral-mediated transfection. Suitable methods for transforming or
15 transfecting host cells can be found in Sambrook *et al.* (*Molecular Cloning: A Laboratory Manual*, 2nd Edition, Cold Spring Harbor Laboratory press (1989)), and other laboratory manuals. Methods for introducing DNA into mammalian cells *in vivo* are also known in the art and can be used to deliver the vector DNA to a subject for gene therapy purposes (discussed further below).

20 For stable transfection of mammalian cells, it is known that, depending upon the expression vector and transfection technique used, only a small fraction of cells may integrate the foreign DNA into their genome. In order to identify and select these integrants, a gene that encodes a selectable marker (*e.g.*, resistance to antibiotics) is generally introduced into the host cells along with the gene of interest. Preferred selectable markers include those that
25 confer resistance to drugs, such as G418, hygromycin and methotrexate. Nucleic acid encoding a selectable marker may be introduced into a host cell on the same vector as that encoding the peptide compound or may be introduced on a separate vector. Cells stably transfected with the introduced nucleic acid can be identified by drug selection (*e.g.*, cells that have incorporated the selectable marker gene will survive, while the other cells die).

30 A nucleic acid of the invention can be delivered to cells *in vivo* using methods known in the art, such as direct injection of DNA, receptor-mediated DNA uptake or viral-mediated transfection. Direct injection has been used to introduce naked DNA into cells *in vivo* (see *e.g.*, Acsadi *et al.* (1991) *Nature* 332: 815-818; Wolff *et al.* (1990) *Science* 247:1465-1468). A delivery apparatus (*e.g.*, a "gene gun") for injecting DNA into cells *in vivo* can be used.
35 Such an apparatus is commercially available (*e.g.*, from BioRad). Naked DNA can also be introduced into cells by complexing the DNA to a cation, such as polylysine, which is coupled to a ligand for a cell-surface receptor (see for example Wu, G. and Wu, C.H. (1988) *J. Biol. Chem.* 263:14621; Wilson *et al.* (1992) *J. Biol. Chem.* 267:963-967; and U.S. Patent No. 5,166,320). Binding of the DNA-ligand complex to the receptor facilitates uptake of the

DNA by receptor-mediated endocytosis. Additionally, a DNA-ligand complex linked to adenovirus capsids which naturally disrupt endosomes, thereby releasing material into the cytoplasm can be used to avoid degradation of the complex by intracellular lysosomes (see for example Curiel *et al.* (1991) *Proc. Natl. Acad. Sci. USA* 88:8850; Cristiano *et al.* (1993) *Proc. Natl. Acad. Sci. USA* 90:2122-2126).

Defective retroviruses are well characterized for use in gene transfer for gene therapy purposes (for a review see Miller, A.D. (1990) *Blood* 76:271). Protocols for producing recombinant retroviruses and for infecting cells *in vitro* or *in vivo* with such viruses can be found in Current Protocols in Molecular Biology, Ausubel, F.M. *et al.* (eds.) Greene Publishing Associates, (1989), Sections 9.10-9.14 and other standard laboratory manuals. Examples of suitable retroviruses include pLJ, pZIP, pWE and pEM which are well known to those skilled in the art. Examples of suitable packaging virus lines include ψ Crip, ψ Cre, ψ 2 and ψ Am. Retroviruses have been used to introduce a variety of genes into many different cell types, including epithelial cells, endothelial cells, lymphocytes, myoblasts, hepatocytes, bone marrow cells, *in vitro* and/or *in vivo* (see for example Eglitis. *et al.* (1985) *Science* 230:1395-1398; Danos and Mulligan (1988) *Proc. Natl. Acad. Sci. USA* 85:6460-6464; Wilson *et al.* (1988) *Proc. Natl. Acad. Sci. USA* 85:3014-3018; Armentano *et al.* (1990) *Proc. Natl. Acad. Sci. USA* 87:6141-6145; Huber *et al.* (1991) *Proc. Natl. Acad. Sci. USA* 88:8039-8043; Ferry *et al.* (1991) *Proc. Natl. Acad. Sci. USA* 88:8377-8381; Chowdhury *et al.* (1991) *Science* 254:1802-1805; van Beusechem *et al.* (1992) *Proc. Natl. Acad. Sci. USA* 89:7640-7644; Kay *et al.* (1992) *Human Gene Therapy* 3:641-647; Dai *et al.* (1992) *Proc. Natl. Acad. Sci. USA* 89:10892-10895; Hwu *et al.* (1993) *J. Immunol.* 150:4104-4115; U.S. Patent No. 4,868,116; U.S. Patent No. 4,980,286; PCT Application WO 89/07136; PCT Application WO 89/02468; PCT Application WO 89/05345; and PCT Application WO 92/07573).

Alternatively, the genome of an adenovirus can be manipulated such that it encodes and expresses a peptide compound but is inactivated in terms of its ability to replicate in a normal lytic viral life cycle. See for example Berkner *et al.* (1988) *BioTechniques* 6:616; Rosenfeld *et al.* (1991) *Science* 252:431-434; and Rosenfeld *et al.* (1992) *Cell* 68:143-155. Suitable adenoviral vectors derived from the adenovirus strain Ad type 5 dl324 or other strains of adenovirus (*e.g.*, Ad2, Ad3, Ad7 etc.) are well known to those skilled in the art. Recombinant adenoviruses are advantageous in that they do not require dividing cells to be effective gene delivery vehicles and can be used to infect a wide variety of cell types, including airway epithelium (Rosenfeld *et al.* (1992) cited *supra*), endothelial cells (Lemarchand *et al.* (1992) *Proc. Natl. Acad. Sci. USA* 89:6482-6486), hepatocytes (Herz and Gerard (1993) *Proc. Natl. Acad. Sci. USA* 90:2812-2816) and muscle cells (Quantin *et al.* (1992) *Proc. Natl. Acad. Sci. USA* 89:2581-2584). Additionally, introduced adenoviral DNA (and foreign DNA contained therein) is not integrated into the genome of a host cell but remains episomal, thereby avoiding potential problems that can occur as a result of

insertional mutagenesis in situations where introduced DNA becomes integrated into the host genome (e.g., retroviral DNA).

Adeno-associated virus (AAV) can also be used for delivery of DNA for gene therapy purposes. AAV is a naturally occurring defective virus that requires another virus, such as an adenovirus or a herpes virus, as a helper virus for efficient replication and a productive life cycle. (For a review see Muzyczka *et al.* *Curr. Topics in Micro. and Immunol.* (1992) 158:97-129). It is also one of the few viruses that may integrate its DNA into non-dividing cells, and exhibits a high frequency of stable integration (see for example Flotte *et al.* (1992) *Am. J. Respir. Cell. Mol. Biol.* 7:349-356; Samulski *et al.* (1989) *J. Virol.* 63:3822-3828; and McLaughlin *et al.* (1989) *J. Virol.* 62:1963-1973). Vectors containing as little as 300 base pairs of AAV can be packaged and can integrate. An AAV vector such as that described in Tratschin *et al.* (1985) *Mol. Cell. Biol.* 5:3251-3260 can be used to introduce DNA into cells. A variety of nucleic acids have been introduced into different cell types using AAV vectors (see for example Hermonat *et al.* (1984) *Proc. Natl. Acad. Sci. USA* 81:6466-6470; Tratschin *et al.* (1985) *Mol. Cell. Biol.* 4:2072-2081; Wondisford *et al.* (1988) *Mol. Endocrinol.* 2:32-39; Tratschin *et al.* (1984) *J. Virol.* 51:611-619; and Flotte *et al.* (1993) *J. Biol. Chem.* 268:3781-3790).

The invention provides a method for treating a subject for a disorder associated with β -amyloidosis, comprising administering to the subject a recombinant expression vector encoding a β -amyloid peptide compound, the compound comprising an amino acid sequence having at least one amino acid deletion compared to β AP₁₋₃₉, such that the β -amyloid peptide compound is synthesized in the subject and the subject is treated for a disorder associated with β -amyloidosis. Preferably, the disorder is Alzheimer's disease. In one embodiment the recombinant expression vector directs expression of the peptide compound in neuronal cells. In another embodiment, the recombinant expression vector directs expression of the peptide compound in glial cells. In yet another embodiment, the recombinant expression vector directs expression of the peptide compound in fibroblast cells.

General methods for gene therapy are known in the art. See for example, U.S. Patent No. 5,399,346 by Anderson *et al.* A biocompatible capsule for delivering genetic material is described in PCT Publication WO 95/05452 by Baetge *et al.* Methods for grafting genetically modified cells to treat central nervous system disorders are described in U.S. Patent No. 5,082,670 and in PCT Publications WO 90/06757 and WO 93/10234, all by Gage *et al.* Isolation and/or genetic modification of multipotent neural stem cells or neuro-derived fetal cells are described in PCT Publications WO 94/02593 by Anderson *et al.*, WO 94/16718 by Weiss *et al.*, and WO 94/23754 by Major *et al.* Fibroblasts transduced with genetic material are described in PCT Publication WO 89/02468 by Mulligan *et al.* Adenovirus vectors for transferring genetic material into cells of the central nervous system are described in PCT Publication WO 94/08026 by Kahn *et al.* Herpes simplex virus vectors suitable for treating neural disorders are described in PCT Publications WO 94/04695 by Kaplitt and WO

90/09441 by Geller *et al.* Promoter elements of the glial fibrillary acidic protein that can confer astrocyte specific expression on a linked gene or gene fragment, and which thus can be used for expression of A β peptides specifically in astrocytes, is described in PCT Publication WO 93/07280 by Brenner *et al.* Furthermore, alternative to expression of an A β peptide to modulate amyloidosis, an antisense oligonucleotide that is complementary to a region of the β -amyloid precursor protein mRNA corresponding to the peptides described herein can be expressed in a subject to modulate amyloidosis. General methods for expressing antisense oligonucleotides to modulate nervous system disorders are described in PCT Publication WO 95/09236.

Alternative to delivery by gene therapy, a peptide compound of the invention comprising an amino acid sequence having at least one amino acid deletion compared to β AP₁₋₃₉ can be delivered to a subject by directly administering the peptide compound to the subject as described further herein for the modified peptide compounds of the invention. The peptide compound can be formulated into a pharmaceutical composition comprising a therapeutically effective amount of the β -amyloid peptide compound and a pharmaceutically acceptable carrier. The peptide compound can be contacted with natural β -amyloid peptides with a β -amyloid peptide compound such that aggregation of the natural β -amyloid peptides is inhibited. Moreover, the peptide compound can be administered to the subject in a therapeutically effective amount such that the subject is treated for a disorder associated with β -amyloidosis, such as Alzheimer's disease.

VIII. Other Embodiments

Although the invention has been illustrated hereinbefore with regard to A β peptide compounds, the principles described, involving attachment of a modifying group(s) to a peptide compound, are applicable to any amyloidogenic protein or peptide as a means to create a modulator compound that modulates, and preferably inhibits, amyloid aggregation. Accordingly, the invention provides modulator compounds that can be used to treat amyloidosis in a variety of forms and clinical settings.

Amyloidosis is a general term used to describe pathological conditions characterized by the presence of amyloid. Amyloid is a general term referring to a group of diverse but specific extracellular protein deposits which are seen in a number of different diseases. Though diverse in their occurrence, all amyloid deposits have common morphologic properties, stain with specific dyes (*e.g.*, Congo red), and have a characteristic red-green birefringent appearance in polarized light after staining. They also share common ultrastructural features and common x-ray diffraction and infrared spectra. Amyloidosis can be classified clinically as primary, secondary, familial and/or isolated. Primary amyloid appears *de novo* without any preceding disorder. Secondary amyloid is that form which appears as a complication of a previously existing disorder. Familial amyloid is a genetically

inherited form found in particular geographic populations. Isolated forms of amyloid are those that tend to involve a single organ system.

Different amyloids are characterized by the type of protein(s) or peptide(s) present in the deposit. For example, as described hereinbefore, amyloid deposits associated with Alzheimer's disease comprise the β -amyloid peptide and thus a modulator compound of the invention for detecting and/or treating Alzheimer's disease is designed based on modification of the β -amyloid peptide. The identities of the protein(s) or peptide(s) present in amyloid deposits associated with a number of other amyloidogenic diseases have been elucidated. Accordingly, modulator compounds for use in the detection and/or treatment of these other amyloidogenic diseases can be prepared in a similar fashion to that described herein for β -AP-derived modulators. *In vitro* assay systems can be established using an amyloidogenic protein or peptide which forms fibrils *in vitro*, analogous to the A β assays described herein. Modulators can be identified using such assay systems, based on the ability of the modulator to disrupt the β -sheet structure of the fibrils. Initially, an entire amyloidogenic protein can be modified or, more preferably, a peptide fragment thereof that is known to form fibrils *in vitro* can be modified (e.g., analogous to A β 1-40 described herein). Amino acid deletion and substitution analyses can then be performed on the modified protein or peptide (analogous to the studies described in the Examples) to delineate an aggregation core domain that is sufficient, when modified, to disrupt fibril formation.

Non-limiting examples of amyloidogenic proteins or peptides, and their associated amyloidogenic disorders, include:

Transthyretin (TTR) - Amyloids containing transthyretin occur in familial amyloid polyneuropathy (Portuguese, Japanese and Swedish types), familial amyloid cardiomyopathy (Danish type), isolated cardiac amyloid and systemic senile amyloidosis. Peptide fragments of transthyretin have been shown to form amyloid fibrils *in vitro*. For example, TTR 10-20 and TTR 105-115 form amyloid-like fibrils in 20-30% acetonitrile/water at room temperature (Jarvis, J.A., *et al.* (1994) *Int. J. Pept. Protein Res.* **44**:388-398). Moreover, familial cardiomyopathy (Danish type) is associated with mutation of Leu at position 111 to Met, and an analogue of TTR 105-115 in which the wildtype Leu at position 111 has been substituted with Met (TTR 105-115Met111) also forms amyloid-like fibrils *in vitro* (see e.g., Hermansen, L.F., *et al.* (1995) *Eur. J. Biochem.* **227**:772-779; Jarvis *et al. supra*). Peptide fragments of TTR that form amyloid fibrils *in vitro* are also described in Jarvis, J.A., *et al.* (1993) *Biochem. Biophys. Res. Commun.* **192**:991-998 and Gustavsson, A., *et al.* (1991) *Biochem. Biophys. Res. Commun.* **175**:1159-1164. A peptide fragment of wildtype or mutated transthyretin that forms amyloid fibrils can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of familial amyloid polyneuropathy (Portuguese, Japanese and Swedish types), familial amyloid cardiomyopathy (Danish type), isolated cardiac amyloid or systemic senile amyloidosis.

Prion Protein (PrP) - Amyloids in a number of spongiform encephalopathies, including scrapie in sheep, bovine spongiform encephalopathy in cows and Creutzfeldt-Jakob disease (CJ) and Gerstmann-Straussler-Scheinker syndrome (GSS) in humans, contain PrP. Limited proteolysis of PrP^{Sc} (the prion protein associated with scrapie) leads to a 27-30 kDa fragment (PrP²⁷⁻³⁰) that polymerizes into rod-shaped amyloids (see *e.g.*, Pan, K.M., *et al.* (1993) *Proc. Natl. Acad. Sci. USA* 90:10962-10966; Gasset, M., *et al.* (1993) *Proc. Natl. Acad. Sci. USA* 90:1-5). Peptide fragments of PrP from humans and other mammals have been shown to form amyloid fibrils *in vitro*. For example, polypeptides corresponding to sequences encoded by normal and mutant alleles of the PRNP gene (encoding the precursor of the prion protein involved in CJ), in the regions of codon 178 and codon 200, spontaneously form amyloid fibrils *in vitro* (see *e.g.*, Goldfarb, L.G., *et al.* (1993) *Proc. Natl. Acad. Sci. USA* 90:4451-4454). A peptide encompassing residues 106-126 of human PrP has been reported to form straight fibrils similar to those extracted from GSS brains, whereas a peptide encompassing residues 127-147 of human PrP has been reported to form twisted fibrils resembling scrapie-associated fibrils (Tagliavini, F., *et al.* (1993) *Proc. Natl. Acad. Sci. USA* 90:9678-9682). Peptides of Syrian hamster PrP encompassing residues 109-122, 113-127, 113-120, 178-191 or 202-218 have been reported to form amyloid fibrils, with the most amyloidogenic peptide being Ala-Gly-Ala-Ala-Ala-Gly-Ala (SEQ ID NO: 17), which corresponds to residues 113-120 of Syrian hamster PrP but which is also conserved in PrP from other species (Gasset, M., *et al.* (1992) *Proc. Natl. Acad. Sci. USA* 89:10940-10944). A peptide fragment of PrP that forms amyloid fibrils can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of scrapie, bovine spongiform encephalopathy, Creutzfeldt-Jakob disease or Gerstmann-Straussler-Scheinker syndrome.

Islet Amyloid Polypeptide (IAPP) (also known as amylin) - Amyloids containing IAPP occur in adult onset diabetes and insulinoma. IAPP is a 37 amino acid polypeptide formed from an 89 amino acid precursor protein (see *e.g.*, Betsholtz, C., *et al.* (1989) *Exp. Cell. Res.* 183:484-493; Westermark, P., *et al.* (1987) *Proc. Natl. Acad. Sci. USA* 84:3881-3885). A peptide corresponding to IAPP residues 20-29 has been reported to form amyloid-like fibrils *in vitro*, with residues 25-29, having the sequence Ala-Ile-Leu-Ser-Ser (SEQ ID NO: 18), being strongly amyloidogenic (Westermark, P., *et al.* (1990) *Proc. Natl. Acad. Sci. USA* 87:5036-5040; Glenner, G.G., *et al.* (1988) *Biochem. Biophys. Res. Commun.* 155:608-614). A peptide fragment of IAPP that forms amyloid fibrils can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of adult onset diabetes or insulinoma.

Atrial Natriuretic Factor (ANF) - Amyloids containing ANF are associated with isolated atrial amyloid (see *e.g.*, Johansson, B., *et al.* (1987) *Biochem. Biophys. Res. Commun.* 148:1087-1092). ANF corresponds to amino acid residues 99-126 (proANF₉₉₋₁₂₆) of the ANF prohormone (proANP₁₋₁₂₆) (Pucci, A., *et al.* (1991) *J. Pathol.* 165:235-

241). ANF, or a fragment thereof, that forms amyloid fibrils can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of isolated atrial amyloid.

Kappa or Lambda Light Chain - Amyloids containing kappa or lambda light chains are associated idiopathic (primary) amyloidosis, myeloma or macroglobulinemia-associated amyloidosis, and primary localized cutaneous nodular amyloidosis associated with Sjogren's syndrome. The structure of amyloidogenic kappa and lambda light chains, including amino acid sequence analysis, has been characterized (see *e.g.*, Buxbaum, J.N., *et al.* (1990) *Ann. Intern. Med.* 112:455-464; Schormann, N., *et al.* (1995) *Proc. Natl. Acad. Sci. USA* 92:9490-9494; Hurle, M.R., *et al.* (1994) *Proc. Natl. Acad. Sci. USA* 91:5446-5450; Liepnieks, J.J., *et al.* (1990) *Mol. Immunol.* 27:481-485; Gertz, M.A., *et al.* (1985) *Scand. J. Immunol.* 22:245-250; Inazumi, T., *et al.* (1994) *Dermatology* 189:125-128). Kappa or lambda light chains, or a peptide fragment thereof that forms amyloid fibrils, can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of idiopathic (primary) amyloidosis, myeloma or macroglobulinemia-associated amyloidosis or primary localized cutaneous nodular amyloidosis associated with Sjogren's syndrome.

Amyloid A - Amyloids containing the amyloid A protein (AA protein), derived from serum amyloid A, are associated with reactive (secondary) amyloidosis (see *e.g.*, Liepnieks, J.J., *et al.* (1995) *Biochim. Biophys. Acta* 1270:81-86), familial Mediterranean Fever and familial amyloid nephropathy with urticaria and deafness (Muckle-Wells syndrome) (see *e.g.*, Linke, R.P., *et al.* (1983) *Lab. Invest.* 48:698-704). Recombinant human serum amyloid A forms amyloid-like fibrils *in vitro* (Yamada, T., *et al.* (1994) *Biochim. Biophys. Acta* 1226:323-329) and circular dichroism studies revealed a predominant β sheet/turn structure (McCubbin, W.D., *et al.* (1988) *Biochem J.* 256:775-783). Serum amyloid A, amyloid A protein or a fragment thereof that forms amyloid fibrils can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of reactive (secondary) amyloidosis, familial Mediterranean Fever and familial amyloid nephropathy with urticaria and deafness (Muckle-Wells syndrome).

Cystatin C - Amyloids containing a variant of cystatin C are associated with hereditary cerebral hemorrhage with amyloidosis of Icelandic type. The disease is associated with a leucine to glycine mutation at position 68 and cystatin C containing this mutation aggregates *in vitro* (Abrahamson, M. and Grubb, A. (1994) *Proc. Natl. Acad. Sci. USA* 91:1416-1420). Cystatin C or a peptide fragment thereof that forms amyloid fibrils can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of hereditary cerebral hemorrhage with amyloidosis of Icelandic type.

β 2 microglobulin - Amyloids containing β 2 microglobulin (β 2M) are a major complication of long term hemodialysis (see *e.g.*, Stein, G., *et al.* (1994) *Nephrol. Dial. Transplant.* 9:48-50; Floege, J., *et al.* (1992) *Kidney Int. Suppl.* 38:S78-S85; Maury, C.P. (1990) *Rheumatol. Int.* 10:1-8). The native β 2M protein has been shown to form amyloid

fibrils *in vitro* (Connors, L.H., *et al.* (1985) *Biochem. Biophys. Res. Commun.* 131:1063-1068; Ono, K., *et al.* (1994) *Nephron* 66:404-407). β 2M, or a peptide fragment thereof that forms amyloid fibrils, can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of amyloidosis associated with long term hemodialysis.

Apolipoprotein A-I (ApoA-I) - Amyloids containing variant forms of ApoA-I have been found in hereditary non-neuropathic systemic amyloidosis (familial amyloid polyneuropathy III). For example, N-terminal fragments (residues 1-86, 1-92 and 1-93) of an ApoA-I variant having a Trp to Arg mutation at position 50 have been detected in amyloids (Booth, D.R., *et al.* (1995) *QJM* 88:695-702). In another family, a leucine to arginine mutation at position 60 was found (Soutar, A.K., *et al.* (1992) *Proc. Natl. Acad. Sci. USA* 89:7389-7393). ApoA-I or a peptide fragment thereof that forms amyloid fibrils can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of hereditary non-neuropathic systemic amyloidosis.

Gelsolin - Amyloids containing variants of gelsolin are associated with familial amyloidosis of Finnish type. Synthetic gelsolin peptides that have sequence homology to wildtype or mutant gelsolins and that form amyloid fibrils *in vitro* are reported in Maury, C.P. *et al.* (1994) *Lab. Invest.* 70:558-564. A nine residue segment surrounding residue 187 (which is mutated in familial gelsolin amyloidosis) was defined as an amyloidogenic region (Maury, *et al.*, *supra*; see also Maury, C.P., *et al.* (1992) *Biochem. Biophys. Res. Commun.* 183:227-231; Maury, C.P. (1991) *J. Clin. Invest.* 87:1195-1199). Gelsolin or a peptide fragment thereof that forms amyloid fibrils can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of familial amyloidosis of Finnish type.

Procalcitonin or calcitonin - Amyloids containing procalcitonin, calcitonin or calcitonin-like immunoreactivity have been detected in amyloid fibrils associated with medullary carcinoma of the thyroid (see *e.g.*, Butler, M. and Khan, S. (1986) *Arch. Pathol. Lab. Med.* 110:647-649; Sletten, K., *et al.* (1976) *J. Exp. Med.* 143:993-998). Calcitonin has been shown to form a nonbranching fibrillar structure *in vitro* (Kedar, I., *et al.* (1976) *Isr. J. Med. Sci.* 12:1137-1140). Procalcitonin, calcitonin or a fragment thereof that forms amyloid fibrils can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of amyloidosis associated with medullary carcinoma of the thyroid.

Fibrinogen - Amyloids containing a variant form of fibrinogen alpha-chain have been found in hereditary renal amyloidosis. An arginine to leucine mutation at position 554 has been reported in amyloid fibril protein isolated from postmortem kidney of an affected individual (Benson, M.D., *et al.* (1993) *Nature Genetics* 3:252-255). Fibrinogen alpha-chain or a peptide fragment thereof that forms amyloid fibrils can be modified as described herein

to create a modulator of amyloidosis that can be used in the detection or treatment of fibrinogen-associated hereditary renal amyloidosis.

Lysozyme - Amyloids containing a variant form of lysozyme have been found in hereditary systemic amyloidosis. In one family the disease was associated with a threonine to isoleucine mutation at position 56, whereas in another family the disease was associated with a histidine to aspartic acid mutation at position 67 (Pepys, M.B., *et al.* (1993) *Nature* 362:553-557). Lysozyme or a peptide fragment thereof that forms amyloid fibrils can be modified as described herein to create a modulator of amyloidosis that can be used in the detection or treatment of lysozyme-associated hereditary systemic amyloidosis.

This invention is further illustrated by the following examples which should not be construed as limiting. A modulator's ability to alter the aggregation of β -amyloid peptide in the assays described below are predictive of the modulator's ability to perform the same function *in vivo*. The contents of all references, patents and published patent applications cited throughout this application are hereby incorporated by reference.

EXAMPLE 1: Construction of β -Amyloid Modulators

A β -amyloid modulator composed of an amino-terminally biotinylated β -amyloid peptide of the amino acid sequence:

DAEFRHDSGYEVHHQKLVFFAEDVGSNKGAIIGLMVGGVV

(positions 1 to 40 of SEQ ID NO: 1) was prepared by solid-phase peptide synthesis using an N α -9-fluorenylmethyloxycarbonyl (Fmoc)-based protection strategy as follows. Starting with 2.5 mmoles of Fmoc-Val-Wang resin, sequential additions of each amino acid were performed using a four-fold excess of protected amino acids. 1-hydroxybenzotriazole (HOBt) and diisopropyl carbodiimide (DIC). Recouplings were performed when necessary as determined by ninhydrin testing of the resin after coupling. Each synthesis cycle was minimally described by a three minute deprotection (25 % piperidine/N-methyl-pyrrolidone (NMP)), a 15 minute deprotection, five one minute NMP washes, a 60 minute coupling cycle, five NMP washes and a ninhydrin test. To a 700 mg portion of the fully assembled peptide-resin, biotin (obtained commercially from Molecular Probes, Inc.) was substituted for an Fmoc-amino acid was coupled by the above protocol. The peptide was removed from the resin by treatment with trifluoroacetic acid (TFA) (82.5 %), water (5 %), thioanisole (5 %), phenol (5 %), ethanedithiol (2.5 %) for two hours followed by precipitation of the peptide in cold ether. The solid was pelleted by centrifugation (2400 rpm x 10 min.), and the ether decanted. It was resuspended in ether, pelleted and decanted a second time. The solid was dissolved in 10 % acetic acid and lyophilized to dryness to yield 230 mg of crude biotinylated peptide. 60 mg of the solid was dissolved in 25 % acetonitrile (ACN) /0.1 % TFA and applied to a C18 reversed phase high performance liquid chromatography (HPLC) column.

Biotinyl β AP₁₋₄₀ was eluted using a linear gradient of 30-45 % acetonitrile/0.1 % TFA over 40 minutes. One primary fraction (4 mg) and several side fractions were isolated. The main fraction yielded a mass spectrum of 4556 (matrix-assisted laser desorption ionization -time of flight) which matches the theoretical (4555) for this peptide.

- 5 A β -amyloid modulator composed of an amino-terminally biotinylated β -amyloid peptide of the amino acid sequence:

DAEFRHDSGYEVHHQ

- (positions 1 to 15 of SEQ ID NO: 1) was prepared on an Advanced ChemTech Model 396 multiple peptide synthesizer using an automated protocol established by the manufacturer for 10 0.025 mmole scale synthesis. Double couplings were performed on all cycles using 2-(1H-benzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (HBTU)/N,N-diisopropylethylamine (DIEA)/HOBt/FMOC-AA in four-fold excess for 30 minutes followed by DIC/HOBt/FMOC-AA in four-fold excess for 45 minutes. The peptide was deprotected and removed from the resin by treatment with TFA/water (95 %/5 %) for three hours and 15 precipitated with ether as described above. The pellet was resuspended in 10 % acetic acid and lyophilized. The material was purified by a preparative HPLC using 15 %-40 % acetonitrile over 80 minutes on a Vydac C18 column (21 x 250 mm). The main isolate eluted as a single symmetrical peak when analyzed by analytical HPLC and yielded the expected molecular weight when analyzed by electrospray mass spectrometry. Result = 2052.6 (2052 20 theoretical).

β -amyloid modulator compounds comprising other regions of the β -AP amino acid sequence (*e.g.*, an A β aggregation core domain) were similarly prepared using the synthesis methods described above. Moreover, modulators comprising other amyloidogenic peptides can be similarly prepared.

25

EXAMPLE 2: Inhibition of β -Amyloid Aggregation by Modulators

- The ability of β -amyloid modulators to inhibit the aggregation of natural β -AP when combined with the natural β -AP was examined in a series of aggregation assays. Natural β - 30 AP (β -AP₁₋₄₀) was obtained commercially from Bachem (Torrance, CA). Amino-terminally biotinylated β -AP modulators were prepared as described in Example 1.

A. Optical Density Assay

- In one assay, β -AP aggregation was measured by determining the increase in turbidity 35 of a solution of natural β -AP over time in the absence or presence of various concentrations of the modulator. Turbidity of the solution was quantitated by determining the optical density at 400 nm ($A_{400 \text{ nm}}$) of the solution over time.

The aggregation of natural β -AP in the absence of modulator was determined as follows. β -AP₁₋₄₀ was dissolved in hexafluoro isopropanol (HFIP; Aldrich Chemical Co.,

Inc.) at 2 mg/ml. Aliquots of the HFIP solution (87 μ l) were transferred to individual 10 mm x 75 mm test tubes. A stream of argon gas was passed through each tube to evaporate the HFIP. To the resulting thin film of peptide, dimethylsulfoxide (DMSO; Aldrich Chemical Co., Inc.) (25 μ l) was added to dissolve the peptide. A 2 mm x 7 mm teflon-coated magnetic stir bar was added to each tube. Buffer (475 μ L of 100 mM NaCl, 10 mM sodium phosphate, pH 7.4) was added to the DMSO solution with stirring. The resulting mixture was stirred continuously and the optical density was monitored at 400 nm to observe the formation of insoluble peptide aggregates.

Alternatively, β -AP₁₋₄₀ was dissolved in DMSO as described above at 1.6 mM (6.9 mg/ml) and aliquots (25 μ l) were added to stirred buffer (475 μ l), followed by monitoring of absorbance at 400 nm.

For inhibition studies in which a β -amyloid modulator was dissolved in solution together with the natural β -AP, the modulators were dissolved in DMSO either with or without prior dissolution in HFIP. These compounds were then added to buffer with stirring, followed by addition of β -AP₁₋₄₀ in DMSO. Alternatively, HFIP solutions of modulators were combined with β -AP₁₋₄₀ in HFIP followed by evaporation and redissolution of the mixture in DMSO. Buffer was then added to the DMSO solution to initiate the assay. The amino-terminally biotinylated β -amyloid peptide modulators N-biotinyl- β AP₁₋₄₀, and N-biotinyl- β AP₁₋₁₅ were tested at concentrations of 1 % and 5 % in the natural β -AP₁₋₄₀ solution.

A representative example of the results is shown graphically in Figure 1, which depicts the inhibition of aggregation of natural β -AP₁₋₄₀ by N-biotinyl- β AP₁₋₄₀. In the absence of the modulator, the optical density of the natural β -AP solution showed a characteristic sigmoidal curve, with a lag time prior to aggregation (approximately 3 hours in Figure 1) in which the $A_{400\text{ nm}}$ was low, followed by rapid increase in the $A_{400\text{ nm}}$, which quickly reached a plateau level, representing aggregation of the natural β amyloid peptides. In contrast, in the presence of as little as 1 % of the N-biotinyl- β AP₁₋₄₀ modulator, aggregation of the natural β amyloid peptides was markedly inhibited, indicated by an increase in the lag time, a decrease in the slope of aggregation and a decrease in the plateau level reached for the turbidity of the solution (see Figure 1). N-biotinyl- β AP₁₋₄₀ at a concentration of 5 % similarly inhibited aggregation of the natural β amyloid peptide. Furthermore, similar results were observed when N-biotinyl- β AP₁₋₁₅ was used as the modulator. These results demonstrate that an N-terminally biotinylated β -AP modulator can effectively inhibit the aggregation of natural β amyloid peptides, even when the natural β amyloid peptides are present at as much as a 100-fold molar excess concentration.

B. Fluorescence Assay

In a second assay, β -AP aggregation was measured using a fluorometric assay essentially as described in Levine, H. (1993) *Protein Science* 2:404-410. In this assay, the

56

dye thioflavine T (ThT) is contacted with the β -AP solution. Association of ThT with aggregated β -AP, but not monomeric or loosely associated β -AP, gives rise to a new excitation (ex) maximum at 450 nm and an enhanced emission (em) at 482 nm, compared to the 385 nm (ex) and 445 nm (em) for the free dye. β -AP aggregation was assayed by this method as follows. Aliquots (2.9 μ l) of the solutions used in the aggregation assays as described above in section A were removed from the samples and diluted in 200 μ l of potassium phosphate buffer (50 mM, pH 7.0) containing thioflavin T (10 μ M; obtained commercially from Aldrich Chemical Co., Inc.). Excitation was set at 450 nm and emission was measured at 482 nm. Similar to the results observed with the optical density assay described above in section A, as little as 1 % of the N-biotinylated β -AP modulators was effective at inhibiting the aggregation of natural β amyloid peptides using this fluorometric assay.

C. Static Aggregation Assay

In a third assay, β -AP aggregation was measured by visualization of the peptide aggregates using SDS-polyacrylamide gel electrophoresis (SDS-PAGE). In this assay, β -AP solutions were allowed to aggregate over a period of time and then aliquots of the reaction were run on a standard SDS-PAGE gel. Typical solution conditions were 200 μ M of β -AP₁₋₄₀ in PBS at 37 °C for 8 days or 200 μ M β -AP₁₋₄₀ in 0.1 M sodium acetate at 37 °C for 3 days. The peptide aggregates were visualized by Coomassie blue staining of the gel or, for β -AP solutions that included a biotinylated β -AP modulator, by western blotting of a filter prepared from the gel with a streptavidin-peroxidase probe, followed by a standard peroxidase assay. The β -AP aggregates are identifiable as high molecular weight, low mobility bands on the gel, which are readily distinguishable from the low molecular weight, high mobility β -AP monomer or dimer bands.

When natural β -AP₁₋₄₀ aggregation was assayed by this method in the absence of any β amyloid modulators, high molecular weight aggregates were readily detectable on the gel. In contrast, when N-biotinyl- β -AP₁₋₄₀ modulator self-aggregation was assayed (*i.e.*, aggregation of the N-biotinyl peptide alone, in the absence of any natural β -AP), few if any high molecular weight aggregates were observed, indicating that the ability of the modulator to self-aggregate is significantly reduced compared to natural β -AP. Finally, when aggregation of a mixture of natural β -AP₁₋₄₀ and N-biotinylated β -AP₁₋₄₀ was assayed by this method, reduced amounts of the peptide mixture associated into high molecular weight aggregates, thus demonstrating that the β amyloid modulator is effective at inhibiting the aggregation of the natural β amyloid peptides.

EXAMPLE 3: Neurotoxicity Analysis of β -Amyloid Modulators

The neurotoxicity of the β -amyloid modulators is tested in a cell-based assay using the neuronal precursor cell line PC-12, or primary neuronal cells, and the viability indicator 3, (4,4-dimethylthiazol-2-yl)2,5-diphenyl-tetrazolium bromide (MTT). (See Shearman, M.S. *et al.* (1994) *Proc. Natl. Acad. Sci. USA* 91:1470-1474; Hansen, M.B. *et al.* (1989) *J. Immun. Methods* 119:203-210). PC-12 is a rat adrenal pheochromocytoma cell line and is available from the American Type Culture Collection, Rockville, MD (ATCC CRL 1721). MTT (commercially available from Sigma Chemical Co.) is a chromogenic substrate that is converted from yellow to blue in viable cells, which can be detected spectrophotometrically.

To test the neurotoxicity of a β -amyloid modulator (either alone or combined with natural β -AP), cells first are plated in 96-well plates at 7,000-10,000 cells/well and allowed to adhere by overnight culture at 37 °C. Serial dilutions of freshly dissolved or "aged" modulators (either alone or combined with natural β -AP) in phosphate buffered saline (PBS) are added to the wells in triplicate and incubation is continued for two or more days. Aged modulators are prepared by incubating an aqueous solution of the modulator at 37 °C undisturbed for a prolonged period (*e.g.*, five days or more). For the final two hours of exposure of the cells to the modulator preparation, MTT is added to the media to a final concentration of 1 mg/ml and incubation is continued at 37 °C. Following the two hour incubation with MTT, the media is removed and the cells are lysed in isopropanol/0.4N HCl with agitation. An equal volume of PBS is added to each well and the absorbance of each well at 570 nm is measured to quantitate viable cells. Alternatively, MTT is solubilized by addition of 50 % N,N-dimethyl formamide/20 % sodium dodecyl sulfate added directly to the media in the wells and viable cells are likewise quantitated by measuring absorbance at 570 nm. The relative neurotoxicity of a β -amyloid modulator (either alone or in combination with natural β -AP) is determined by comparison to natural β -AP alone (*e.g.*, β 1-40, β 1-42), which exhibits neurotoxicity in this assay and thus can serve as a positive control.

EXAMPLE 4: Syntheses of Additional Modified β -Amyloid Peptide Compounds

In this example, a series of modified β -APs, having a variety of *N*-terminal or random side chain modifications were synthesized.

A series of *N*-terminally modified β -amyloid peptides was synthesized using standard methods. Fully-protected resin-bound peptides corresponding to A β (1-15) and A β (1-40) were prepared as described in Example 1 on Wang resin to eventually afford carboxyl terminal peptide acids. Small portions of each peptide resin (13 and 20 μ moles, respectively) were aliquoted into the wells of the reaction block of an Advanced ChemTech Model 396 Multiple Peptide Synthesizer. The *N*-terminal Fmoc protecting group of each sample was removed in the standard manner with 25% piperidine in NMP followed by extensive washing

with NMP. The unprotected *N*-terminal α -amino group of each peptide-resin sample was modified using one of the following methods:

Method A, coupling of modifying reagents containing free carboxylic acid groups: The modifying reagent (five equivalents) was predissolved in NMP, DMSO or a mixture of these two solvents. HOBT and DIC (five equivalents of each reagent) were added to the dissolved modifier and the resulting solution was added to one equivalent of free-amino peptide-resin. Coupling was allowed to proceed overnight, followed by washing. If a ninhydrin test on a small sample of peptide-resin showed that coupling was not complete, the coupling was repeated using 1-hydroxy-7-azabenzotriazole (HOAt) in place of HOBT.

Method B, coupling of modifying reagents obtained in preactivated forms: The modifying reagent (five equivalents) was predissolved in NMP, DMSO or a mixture of these two solvents and added to one equivalent of peptide-resin. Diisopropylethylamine (DIEA; six equivalents) was added to the suspension of activated modifier and peptide-resin. Coupling was allowed to proceed overnight, followed by washing. If a ninhydrin test on a small sample of peptide-resin showed that coupling was not complete, the coupling was repeated.

After the second coupling (if required) the *N*-terminally modified peptide-resins were dried at reduced pressure and cleaved from the resin with removal of side-chain protecting groups as described in Example 1. Analytical reversed-phase HPLC was used to confirm that a major product was present in the resulting crude peptides which were purified using Millipore Sep-Pak cartridges or preparative reverse-phase HPLC. Mass spectrometry was used to confirm the presence of the desired compound in the product.

Method A was used to couple *N*-acetylneuraminic acid, cholic acid, *trans*-4-cotininecarboxylic acid, 2-imino-1-imidazolidineacetic acid, (*S*)-(-)-indoline-2-carboxylic acid, (-)-menthoxyacetic acid, 2-norbornaneacetic acid, γ -oxo-5-acenaphthenebutyric acid, (-)-2-oxo-4-thiazolidinecarboxylic acid, and tetrahydro-3-furoic acid. Method B was used to couple 2-iminobiotin-*N*-hydroxysuccinimide ester, diethylenetriaminepentaacetic dianhydride, 4-morpholinecarbonyl chloride, 2-thiopheneacetyl chloride, and 2-thiophenesulfonyl chloride.

In a manner similar to the construction of *N*-terminally modified A β (1-15) and A β (1-40) peptides described above, *N*-fluoresceinyl A β (1-15) and A β (1-40) were prepared in two alternative manners using the preactivated reagents 5-(and 6)-carboxyfluorescein succinimidyl ester and fluorescein-5-isothiocyanate (FITC Isomer I). Both reagents were obtained from Molecular Probes Inc. Couplings were performed using four equivalents of reagent per equivalent of peptide-resin with DIEA added to make the reaction solution basic to wet pH paper. Couplings of each reagent to A β (1-15)-resin appeared to be complete after a single overnight coupling. Coupling to A β (1-40)-resin was slower as indicated by a positive ninhydrin test and both reagents were recoupled to this peptide-resin overnight in

tetrahydrofuran-NMP (1:2 v/v). The resulting *N*-terminally modified peptide-resins were cleaved, deprotected and purified as described in Example A.

In addition to the *N*-fluoresceinyl A β peptides described above, a β -amyloid modulator comprised of random modification of A β (1-40) with fluorescein was prepared. A β (1-40) purchased from Bachem was dissolved in DMSO at approximately 2 mg/mL. 5-(and-6)-Carboxyfluorescein purchased from Molecular Probes was added in a 1.5 molar excess and DIEA was added to make the solution basic to wet pH paper. The reaction was allowed to proceed for 1 hour at room temperature and was then quenched with triethanolamine. The product was added to assays as this crude mixture.

β -amyloid modulator compounds comprising other regions of the β -AP amino acid sequence (*e.g.*, an A β aggregation core domain) were similarly prepared using the synthesis methods described above. Moreover, modulators comprising other amyloidogenic peptides can be similarly prepared.

EXAMPLE 5: Identification of Additional β -Amyloid Modulators

In this Example, two assays of A β aggregation were used to identify β -amyloid modulators which can inhibit this process.

The first assay is referred to as a seeded static assay (SSA) and was performed as follows:

To prepare a solution of A β monomer, the appropriate quantity of A β (1-40) peptide (Bachem) was weighed out on a micro-balance (the amount was corrected for the amount of water in the preparation, which, depending on lot number, was 20-30% w/w). The peptide was dissolved in 1/25 volume of dimethylsulfoxide (DMSO), followed by water to 1/2 volume and 1/2 volume 2x PBS (10x PBS: NaCl 137 mM, KCl 2.7 mM Na₂HPO₄ • 7H₂O 4.3 mM, KH₂PO₄ 1.4 mM pH 7.2) to a final concentration of 200 μ M.

To prepare a stock seed, 1 ml of the above A β monomer preparation, was incubated for 8 days at 37 °C and sheared sequentially through an 18, 23, 26 and 30 gauge needle 25, 25, 50, and 100 times respectively. 2 μ l samples of the sheared material was taken for fluorescence measurements after every 50 passes through the 30 gauge needle until the fluorescence units (FU) had plateaued (approx. 100-150x).

To prepare a candidate inhibitor, the required amount of candidate inhibitor was weighed out and the stock dissolved in 1x PBS to a final concentration of 1 mM (10x stock). If insoluble, it was dissolved in 1/10 volume of DMSO and diluted in 1x PBS to 1 mM. A further 1/10 dilution was also prepared to test each candidate at both 100 μ M and 10 μ M.

For the aggregation assay, each sample was set up in triplicate [50 μ l of 200 μ M monomer, 125 FU sheared seed (variable quantity dependent on the batch of seed, routinely 3-6 μ l), 10 μ l of 10x inhibitor solution, final volume made up to 100 μ l with 1x PBS]. Two concentrations of each inhibitor were tested 100 μ M and 10 μ M, equivalent to a 1:1 and a

60

1:10 molar ratio of monomer to inhibitor. The controls included an unseeded reaction to confirm that the fresh monomer contained no seed, and a seeded reaction in the absence of inhibitor, as a reference to compare against putative inhibitors. The assay was incubated at 37 °C for 6 h, taking 2 µl samples hourly for fluorescence measurements. To measure
5 fluorescence, a 2 µl sample of Aβ was added to 400 µl of Thioflavin-T solution (50 mM Potassium Phosphate 10 mM Thioflavin-T pH 7.5). The samples were vortexed and the fluorescence was read in a 0.5 ml micro quartz cuvette at EX 450 nm and EM 482 nm (Hitachi 4500 Fluorimeter). β-aggregation results in enhanced emission of Thioflavin-T. Accordingly, samples including an effective inhibitor compound exhibit reduced emission as
10 compared to control samples without the inhibitor compound.

The second assay is referred to as a shaken plate aggregation assay and was performed as follows:

Aβ(1-40) peptide from Bachem (Torrance, CA) was dissolved in HFIP (1,1,1,3,3,3-Hexafluoro-2-propanol; Aldrich 10.522-8) at a concentration of 2 mg peptide/ml and incubated
15 at room temperature for 30 min. HFIP solubilized peptide was sonicated in a waterbath sonicator for 5 min at highest setting, then evaporated to dryness under a stream of argon. The peptide film was resuspended in anhydrous dimethylsulfoxide (DMSO) at a concentration of 6.9 mg/ml, sonicated for 5 min as before, then filtered through a 0.2 micron nylon syringe filter
20 (VWR cat. No. 28196-050). Candidate inhibitors were dissolved directly in DMSO, generally at a molar concentration 4 times that of the Aβ(1-40) peptide.

Candidates were assayed in triplicate. For each candidate to be tested, 4 parts Aβ(1-40) peptide in DMSO were combined with 1 part candidate inhibitor in DMSO in a glass vial, and mixed to produce a 1:1 molar ratio of Aβ peptide to candidate. For different molar ratios,
25 candidates were diluted with DMSO prior to addition to Aβ(1-40), in order to keep the final DMSO and Aβ(1-40) concentrations constant. Into an ultra low binding 96 well plate (Corning Costar cat. No. 2500, Cambridge MA) 100 µl PTL buffer (150 mM NaCl, 10 mM NaH₂PO₄; pH 7.4) was aliquotted per well. For each candidate, 10 µl of peptide mixture in DMSO was aliquotted into each of three wells containing buffer. The covered plate was vigorously
30 vortexed on a plate shaker at high speed for 30 seconds. An additional 100 µl of PTL buffer was added to each well and again the plate was vortexed vigorously for 30 sec. Absorbance at 405 nm was immediately read in a plate reader for a baseline reading. The plate was returned to the plate shaker and vortexed at moderate speed for 5 hours at room temperature, with absorbance readings taken at 15-20 min intervals. Increased absorbance indicated aggregation.
35 Accordingly, effective inhibitor compounds cause a decrease in absorbance in the test sample as compared to a control sample without the inhibitor compound.

Representative results of the static seeded assay and shaken plate assay with preferred β-amyloid modulators are shown below in Table I.

(6)

TABLE I

Candidate Inhibitor	A β Amino Acids	Modifying Reagent	Effect in shaken plate assay	Effect in Seeded Static Assay *
174	A β 1-15	Cholic acid	Complete inhibition at 100% conc	++
176	A β 1-15	Diethylene-triamine penta acetic acid	Decreased Plateau	++
180	A β 1-15	(-)-Menthoxycetic acid	None	++
190	A β 1-15	Fluorescein carboxylic acid (FICO)	Decreased Plateau	++
220	A β 16-40 mutant	h-EVHHHHQKK-[A β (16-40)]-OH	Complete inhibition at 100%, increased lag at 10 %	++
224	A β 1-40 mutant	F ₁₉ F ₂₀ ->T ₁₉ T ₂₀	Increased lag	++
233	A β 6-20	Acetic acid	accelerated aggregation at 10% conc	++

* ++ = A strong inhibitor of aggregation. The rate of aggregation in the presence of the inhibitor was decreased compared to the control by at least 30-50%

These results indicate that β -APs modified by a wide variety of N-terminal modifying groups are effective at modulating β -amyloid aggregation.

10 **EXAMPLE 6: Additional β -Amyloid Aggregation Assays**

Most preferably, the ability of β -amyloid modulator compounds to modulate (*e.g.*, inhibit or promote) the aggregation of natural β -AP when combined with the natural β -AP is examined in one or both of the aggregation assays described below. Natural β -AP (β -AP₁₋₄₀) for use in the aggregation assays is commercially available from Bachem (Torrance, CA).

A. Nucleation Assay

The nucleation assay is employed to determine the ability of test compounds to alter (*e.g.* inhibit) the early events in formation of β -AP fibers from monomeric β -AP.

20 Characteristic of a nucleated polymerization mechanism, a lag time is observed prior to

67

nucleation, after which the peptide rapidly forms fibers as reflected in a linear rise in turbidity. The time delay before polymerization of β -AP monomer can be quantified as well as the extent of formation of insoluble fiber by light scattering (turbidity). Polymerization reaches equilibrium when the maximum turbidity reaches a plateau. The turbidity of a solution of natural β -AP in the absence or presence of various concentrations of a β -amyloid modulator compound is determined by measuring the apparent absorbance of the solution at 405nm ($A_{405\text{ nm}}$) over time. The threshold of sensitivity for the measurement of turbidity is in the range of 15-20 μ M β -AP. A decrease in turbidity over time in the presence of the modulator, as compared to the turbidity in the absence of the modulator, indicates that the modulator inhibits formation of β -AP fibers from monomeric β -AP. This assay can be performed using stirring or shaking to accelerate polymerization, thereby increasing the speed of the assay. Moreover the assay can be adapted to a 96-well plate format to screen multiple compounds.

To perform the nucleation assay, first $A\beta_{1-40}$ peptide is dissolved in HFIP (1,1,1,3,3,3-Hexafluoro-2-propanol; Aldrich 10.522-8) at a concentration of 2 mg peptide/ml and incubated at room temperature for 30 min. HFIP-solubilized peptide is sonicated in a waterbath sonicator for 5 min at highest setting, then evaporated to dryness under a stream of argon. The peptide film is resuspended in anhydrous dimethylsulfoxide (DMSO) at a concentration of 6.9 mg/ml (25x concentration), sonicated for 5 min as before, then filtered through a 0.2 micron nylon syringe filter (VWR cat. No. 28196-050). Test compounds are dissolved in DMSO at a 100x concentration. Four volumes of 25x $A\beta_{1-40}$ peptide in DMSO are combined with one volume of test compound in DMSO in a glass vial, and mixed to produce a 1:1 molar ratio of $A\beta$ peptide to test compound. For different molar ratios, test compounds are diluted with DMSO prior to addition to $A\beta_{1-40}$, in order to keep the final DMSO and $A\beta_{1-40}$ concentrations constant. Control samples do not contain the test compound. Ten microliters of the mixture is then added to the bottom of a well of a Corning Costar ultra low binding 96-well plate (Corning Costar, Cambridge MA; cat. No. 2500). Ninety microliters of water is added to the well, the plate is shaken on a rotary shaker at a constant speed at room temperature for 30 seconds, an additional 100 μ l of 2x PTL buffer (20 mM NaH_2PO_4 , 300 mM NaCl, pH 7.4) is added to the well, the plate is reshaken for 30 seconds and a baseline ($t=0$) turbidity reading is taken by measuring the apparent absorbance at 405 nm using a Bio-Rad Model 450 Microplate Reader. The plate is then returned to the shaker and shaken continuously for 5 hours. Turbidity readings are taken at 15 minute intervals.

β -amyloid aggregation in the absence of any modulators results in enhanced turbidity of the natural β -AP solution (*i.e.*, an increase in the apparent absorbance at 405 nm over time). Accordingly, a solution including an effective inhibitory modulator compound exhibits reduced turbidity as compared to the control sample without the modulator

63

compound (*i.e.*, less apparent absorbance at 405 nm over time as compared to the control sample).

B. Seeded Extension Assay

5 The seeded extension assay can be employed to measure the rate of A β fiber formed in a solution of A β monomer following addition of polymeric A β fiber "seed". The ability of test compounds to prevent further deposition of monomeric A β to previously deposited amyloid is determined using a direct indicator of β -sheet formation using fluorescence. In contrast with the nucleation assay, the addition of seed provides immediate nucleation and
10 continued growth of preformed fibrils without the need for continuous mixing, and thus results in the absence of a lag time before polymerization starts. Since this assay uses static polymerization conditions, the activity of positive compounds in the nucleation assay can be confirmed in this second assay under different conditions and with an additional probe of amyloid structure.

15 In the seeded extension assay, monomeric A β_{1-40} is incubated in the presence of a "seed" nucleus (approximately ten mole percent of A β that has been previously allowed to polymerize under controlled static conditions). Samples of the solution are then diluted in thioflavin T (Th-T). The polymer-specific association of Th-T with A β produces a fluorescent complex that allows the measurement of the extent of fibril formation (Levine, H.
20 (1993) *Protein Science* 2:404-410). In particular, association of Th-T with aggregated β -AP, but not monomeric or loosely associated β -AP, gives rise to a new excitation (ex) maximum at 450 nm and an enhanced emission (em) at 482 nm, compared to the 385 nm (ex) and 445 nm (em) for the free dye. Small aliquots of the polymerization mixture contain sufficient
25 fibril to be mixed with Th-T to allow the monitoring of the reaction mixture by repeated sampling. A linear growth curve is observed in the presence of excess monomer. The formation of thioflavin T responsive β -sheet fibrils parallels the increase in turbidity observed using the nucleation assay.

 A solution of A β monomer for use in the seeded extension assay is prepared by dissolving an appropriate quantity of A β_{1-40} peptide in 1/25 volume of dimethylsulfoxide
30 (DMSO), followed by water to 1/2 volume and 1/2 volume 2x PBS (10x PBS: NaCl 137 mM, KCl 2.7 mM Na₂HPO₄ • 7H₂O 4.3 mM, KH₂PO₄ 1.4 mM pH 7.2) to a final concentration of 200 μ M. To prepare the stock seed, 1 ml of the A β monomer preparation, is incubated for approximately 8 days at 37 °C and sheared sequentially through an 18, 23, 26 and 30 gauge
35 needle 25, 25, 50, and 100 times respectively. 2 μ l samples of the sheared material is taken for fluorescence measurements after every 50 passes through the 30 gauge needle until the fluorescence units (FU) plateau (approx. 100-150x). Test compounds are prepared by dissolving an appropriate amount of test compound in 1x PBS to a final concentration of 1 mM (10x stock). If insoluble, the compound is dissolved in 1/10 volume of DMSO and

64

diluted in 1x PBS to 1 mM. A further 1/10 dilution is also prepared to test each candidate at both 100 μ M and 10 μ M.

To perform the seeded extension assay, each sample is set up with 50 μ l of 200 μ M monomer, 125 FU sheared seed (a variable quantity dependent on the batch of seed, routinely 3-6 μ l) and 10 μ l of 10x modulator solution. The sample volume is then adjusted to a final volume of 100 μ l with 1x PBS. Two concentrations of each modulator typically are tested: 100 μ M and 10 μ M, equivalent to a 1:1 and a 1:10 molar ratio of monomer to modulator. The controls include an unseeded reaction to confirm that the fresh monomer contains no seed, and a seeded reaction in the absence of any modulators, as a reference to compare against candidate modulators. The assay is incubated at 37 °C for 6 h. taking 2 μ l samples hourly for fluorescence measurements. To measure fluorescence, a 2 μ l sample of A β is added to 400 μ l of Thioflavin-T solution (50 mM Potassium Phosphate 10 mM Thioflavin-T pH 7.5). The samples are vortexed and the fluorescence is read in a 0.5 ml micro quartz cuvette at EX 450 nm and EM 482 nm (Hitachi 4500 Fluorimeter).

β -amyloid aggregation results in enhanced emission of Thioflavin-T. Accordingly, samples including an effective inhibitory modulator compound exhibit reduced emission as compared to control samples without the modulator compound.

EXAMPLE 7: Effect of Different Amino Acid Subregions of A β Peptide on the Inhibitory Activity of β -Amyloid Modulator Compounds

To determine the effect of various subregions of A β_{1-40} on the inhibitory activity of a β -amyloid modulator, overlapping A β peptide 15mers were constructed. For each 15mer, four different amino-terminal modifiers were tested: a cholyl group, an iminobiotinyl group, an N-acetyl neuraminy group (NANA) and a 5-(and 6-)-carboxyfluoresceinyl group (FICO). The modulators were evaluated in the nucleation and seeded extension assays described in Example 6.

The results of the nucleation assays are summarized below in Table II. The concentration of A β_{1-40} used in the assays was 50 μ M. The "mole %" value listed in Table II refers to the % concentration of the test compound relative to A β_{1-40} . Accordingly, 100% indicates that A β_{1-40} and the test compound were equimolar. Mole % values less than 100% indicate that A β_{1-40} was in molar excess relative to the test compound (*e.g.*, 10% indicates that A β_{1-40} was in 10-fold molar excess relative to the test compound). The results of the nucleation assays for each test compound are presented in Table II in two ways. The "fold increase in lag time", which is a measure of the ability of the compound to delay the onset of aggregation, refers to the ratio of the observed lag time in the presence of the test compound to the observed lag time in the control without the test compound. Accordingly a fold increase in lag time of 1.0 indicates no change in lag time, whereas numbers > 1.0 indicate an increase in lag time. The "% inhibition of plateau", which is a measure of the ability of the

65

compound to decrease the total amount of aggregation, refers to the reduction of the final turbidity in the presence of the test compound expressed as a percent of the control without the test compound. Accordingly, an inhibitor that abolishes aggregation during the course of the assay will have a % inhibition of 100. N-terminally modified A β subregions which

5 exhibited inhibitory activity are indicated in bold in Table II.

Table II

<u>Reference #</u>	<u>N-terminal Modification</u>	<u>Aβ Peptide</u>	<u>Mole %</u>	<u>Fold Increase in Lag Time</u>	<u>% Inhibition of Plateau</u>
PPI-174	cholyl	Aβ₁₋₁₅	100	>4.5	100

PPI-268	FICO	A β ₆₋₂₀	100	1.9	~0
PPI-273	FICO	Aβ₁₁₋₂₅	100	1.7	34
PPI-278	FICO	Aβ₁₆₋₃₀	100	1.6	59
PPI-283	FICO	Aβ₂₁₋₃₅	100	1.2	25
PPI-288	FICO	Aβ₂₆₋₄₀	100	2	75

These results indicate that certain subregions of A β ₁₋₄₀, when modified with an appropriate modifying group, are effective at inhibiting the aggregation of A β ₁₋₄₀. A cholyl group was an effective modifying group for several subregions. Cholic acid alone was tested for inhibitory activity but had no effect on A β aggregation. The A β ₆₋₂₀ subregion exhibited high levels of inhibitory activity when modified with several different modifying groups (cholyl, NANA, iminobiotinyl), with cholyl-A β ₆₋₂₀ (PPI-264) being the most active form.

Accordingly, this modulator compound was chosen for further analysis, described in Example 8.

EXAMPLE 8: Identification of a Five Amino Acid Subregion of A β Peptide

Sufficient for Inhibitory Activity of a β -Amyloid Modulator Compound

To further delineate a minimal subregion of cholyl-A β_{6-20} sufficient for inhibitory activity, a series of amino terminal and carboxy terminal amino acid deletions of cholyl-A β_{6-20} were constructed. The modulators all had the same cholyl amino-terminal modification. Additionally, for the peptide series having carboxy terminal deletions, the carboxy terminus was further modified to an amide. The modulators were evaluated as described in Example 7 and the results are summarized below in Table III, wherein the data is presented as described in Example 7.

Table III

Ref. #	N-Term. Mod.	A β Peptide	C-Term. Mod.	Mole %	Fold Increase in Lag Time	% Inhibition of Plateau
PPI-264	cholyl	A β_{6-20}	-	100	>4.5	100
				10	2	43
PPI-341	cholyl	A β_{7-20}	-	100	>4.5	100
				33	2	~0
PPI-342	cholyl	A β_{8-20}	-	100	1.5	~0
				33	2.1	~0
PPI-343	cholyl	A β_{9-20}	-	33	2.0	~0
PPI-344	cholyl	A β_{10-20}	-	33	2.1	~0
PPI-345	cholyl	A β_{11-20}	-	33	1.5	~0
PPI-346	cholyl	A β_{12-20}	-	33	2.1	~0
PPI-347	cholyl	A β_{13-20}	-	33	2.6	~0
PPI-348	cholyl	A β_{14-20}	-	33	2.0	49
PPI-349	cholyl	A β_{15-20}	-	33	2.3	50
PPI-350	cholyl	A β_{16-20}	-	38	3.4	23
PPI-296	cholyl	A β_{6-20}	amide	33	1.8	~0
PPI-321	cholyl	A β_{6-19}	amide	33	1.4	~0
PPI-325	cholyl	A β_{6-17}	amide	33	1.8	~0
PPI-331	cholyl	A β_{6-14}	amide	33	1.0	29
PPI-339	cholyl	A β_{6-10}	amide	33	1.1	13

These results indicate that activity of the modulator is maintained when amino acid residue 6 is removed from the amino terminal end of the modulator (*i.e.*, cholyl-A β_{7-20} retained activity) but activity is lost as the peptide is deleted further at the amino-terminal end by removal of amino acid position 7 through to amino acid position 12 (*i.e.*, cholyl-A β_{8-20}

67

through cholyl-A β_{13-20} did inhibit the plateau level of A β aggregation). However, further deletion of amino acid position 13 resulted in a compound (*i.e.*, cholyl-A β_{14-20}) in which inhibitory activity is restored. Furthermore, additional deletion of amino acid position 14 (*i.e.*, cholyl-A β_{15-20}) or positions 14 and 15 (*i.e.*, cholyl-A β_{16-20}) still maintained inhibitory activity. Thus, amino terminal deletions of A β_{6-20} identified A β_{16-20} as a minimal subregion which is sufficient for inhibitory activity when appropriately modified. In contrast, carboxy terminal deletion of amino acid position 20 resulted in loss of activity which was not fully restored as the peptide was deleted further at the carboxy-terminal end. Thus, maintenance of position 20 within the modulator may be important for inhibitory activity.

EXAMPLE 9: Identification of a Four Amino Acid Subregion of A β Peptide Sufficient for Inhibitory Activity of a β -Amyloid Modulator Compound

In this example, the smallest effective modulator identified in the studies described in Example 8, cholyl-A β_{16-20} (PPI-350), was analyzed further. Additional amino- and carboxy-terminal deletions were made with cholyl-A β_{16-20} , as well as an amino acid substitution (Val₁₈->Thr), to identify the smallest region sufficient for the inhibitory activity of the modulator. A peptide comprised of five alanine residues, (Ala)₅, modified at its amino-terminus with cholic acid, was used as a specificity control. The modulators were evaluated as described in Example 7 and the results are summarized below in Table IV, wherein the data is presented as described in Example 7.

Table IV

Ref. #	N-Term. Mod.	A β Peptide	C-Term. Mod.	Mole %	Fold Increase in Lag Time	% Inhibition of Plateau
PPI-264	cholyl	A β_{6-20}	-	10	2.0	43
PPI-347	cholyl	A β_{13-20}	-	10	2.2	57
PPI-349	cholyl	A β_{15-20}	-	100	>5.0	100
				33	2.6	35
				10	2.1	~0
PPI-350	cholyl	A β_{16-20}	-	100	>5.0	100
				10	2.4	40
PPI-368	cholyl	A β_{17-21}	-	100	>5.0	100
PPI-374	imino-biotinyl	A β_{16-20}	-	100	1.3	86
PPI-366	cholyl	A β_{15-19}	-	100	3.1	~0
				10	1.6	~0
PPI-369	cholyl	A β_{16-20} (Val ₁₈ ->Thr)	-	100	~1	~0
PPI-370	cholyl	A β_{16-20} (Phe ₁₉ ->Ala)	-	100	2.6	73
PPI-365	cholyl	(Ala) ₅	-	100	~1	~0

68

PPI-319	- cholyl	A β ₁₆₋₂₀	amide	33	5.6	~0
				10	2.7	~0
PPI-321	cholyl	A β ₁₆₋₁₉	amide	100	1.2	~0
PPI-377	-	A β ₁₆₋₂₀	-	100	~1	~0

As shown in Table IV, cholyl-A β ₁₆₋₂₀ (PPI-350) and cholyl-A β ₁₇₋₂₁ (PPI-368) both exhibited inhibitory activity, indicating that the four-amino acid minimal subregion of positions 17-20 is sufficient for inhibitory activity. Loss of position 20 (*e.g.*, in PPI-366 and PPI-321) resulted in loss of inhibitory activity, demonstrating the importance of position 20. Moreover, mutation of valine at position 18 to threonine (in PPI-369) also resulted in loss of activity, demonstrating the importance of position 18. In contrast, mutation of phenylalanine at position 19 to alanine (cholyl-A β ₁₆₋₂₀ Phe₁₉->Ala; PPI-370) resulted in a compound which still retained detectable inhibitory activity. Accordingly, the phenylalanine at position 19 is more amenable to substitution, preferably with another hydrophobic amino acid residue. Cholyl-penta-alanine (PPI-365) showed no inhibitory activity, demonstrating the specificity of the A β peptide portion of the modulator. Moreover, unmodified A β ₁₆₋₂₀ (PPI-377) was not inhibitory, demonstrating the functional importance of the amino-terminal modifying group. The specific functional group influenced the activity of the modulator. For example, iminobiotinyl-A β ₁₆₋₂₀ (PPI-374) exhibited inhibitory activity similar to cholyl-A β ₁₆₋₂₀, whereas an N-acetyl neuraminic acid (NANA)-modified A β ₁₆₋₂₀ was not an effective inhibitory modulator (not listed in Table IV). A C-terminal amide derivative of cholyl-A β ₁₆₋₂₀ (PPI-319) retained high activity in delaying the lag time of aggregation, indicating that the carboxy-terminus of the modulator can be derivatized without loss of inhibitory activity. Although this amide-derivatized compound did not inhibit the overall plateau level of aggregation over time, the compound was not tested at concentrations higher than mole 33 %. Higher concentrations of the amide-derivatized compound are predicted to inhibit the overall plateau level of aggregation, similar to cholyl-A β ₁₆₋₂₀ (PPI-350).

EXAMPLE 10: Effect of β -Amyloid Modulators on the Neurotoxicity of Natural β -Amyloid Peptide Aggregates

The neurotoxicity of natural β -amyloid peptide aggregates, in either the presence or absence of a β -amyloid modulator, is tested in a cell-based assay using either a rat or human neuronally-derived cell line (PC-12 cells or NT-2 cells, respectively) and the viability indicator 3-(4,4-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT). (See *e.g.*, Shearman, M.S. *et al.* (1994) *Proc. Natl. Acad. Sci. USA* 91:1470-1474; Hansen, M.B. *et al.* (1989) *J. Immun. Methods* 119:203-210 for a description of similar cell-based viability assays). PC-12 is a rat adrenal pheochromocytoma cell line and is available from the American Type Culture Collection, Rockville, MD (ATCC CRL 1721). MTT (commercially

GA

available from Sigma Chemical Co.) is a chromogenic substrate that is converted from yellow to blue in viable cells, which can be detected spectrophotometrically.

To test the neurotoxicity of natural β -amyloid peptides, stock solutions of fresh $A\beta$ monomers and aged $A\beta$ aggregates were first prepared. $A\beta_{1-40}$ in 100% DMSO was prepared from lyophilized powder and immediately diluted in one half the final volume in H_2O and then one half the final volume in 2X PBS so that a final concentration of 200 μM peptide, 4% DMSO is achieved. Peptide prepared in this way and tested immediately on cells is referred to as "fresh" $A\beta$ monomer. To prepare "aged" $A\beta$ aggregates, peptide solution was placed in a 1.5 ml Eppendorf tube and incubated at 37 °C for eight days to allow fibrils to form. Such "aged" $A\beta$ peptide can be tested directly on cells or frozen at -80°C. The neurotoxicity of fresh monomers and aged aggregates were tested using PC12 and NT2 cells. PC12 cells were routinely cultured in Dulbecco's modified Eagle's medium (DMEM) containing 10% horse serum, 5% fetal calf serum, 4mM glutamine, and 1% gentamycin. NT2 cells were routinely cultured in OPTI-MEM medium (GIBCO BRL CAT. #31985) supplemented with 10% fetal calf serum, 2 mM glutamine and 1% gentamycin. Cells were plated at 10-15,000 cells per well in 90 μL of fresh medium in a 96 -well tissue culture plate 3-4 hours prior to treatment. The fresh or aged $A\beta$ peptide solutions (10 μL) were then diluted 1:10 directly into tissue culture medium so that the final concentration was in the range of 1-10 μM peptide. Cells are incubated in the presence of peptide without a change in media for 48 hours at 37°C. For the final three hours of exposure of the cells to the β -AP preparation, MTT was added to the media to a final concentration of 1 mg/ml and incubation was continued at 37 °C. Following the two hour incubation with MTT, the media was removed and the cells were lysed in 100 μL isopropanol/0.4N HCl with agitation. An equal volume of PBS was added to each well and the plates were agitated for an additional 10 minutes. Absorbance of each well at 570 nm was measured using a microtiter plate reader to quantitate viable cells.

The neurotoxicity of aged (5 day or 8 day) $A\beta_{1-40}$ aggregates alone, but not fresh $A\beta_{1-40}$ monomers alone, was confirmed in an experiment the results of which are shown in Figure 3, which demonstrates that incubating the neuronal cells with increasing amounts of fresh $A\beta_{1-40}$ monomers was not significantly toxic to the cells whereas incubating the cells with increasing amounts of 5 day or 8 day $A\beta_{1-40}$ aggregates led to increasing amount of neurotoxicity. The EC50 for toxicity of aged $A\beta_{1-40}$ aggregates was 1-2 μM for both the PC12 cells and the NT2 cells.

To determine the effect of a β -amyloid modulator compound on the neurotoxicity of $A\beta_{1-40}$ aggregates, a modulator compound, choly1- $A\beta_{6-20}$ (PPI-264), was preincubated with $A\beta_{1-40}$ monomers under standard nucleation assay conditions as described in Example 6 and at particular time intervals post-incubation, aliquots of the β -AP/modulator solution were removed and 1) the turbidity of the solution was assessed as a measure of aggregation and 2) the solution was applied to cultured neuronal cells for 48 hours at which time cell viability

was assessed using MTT to determine the neurotoxicity of the solution. The results of the turbidity analysis are shown in Figure 4, panels A, B and C. In panel A, A β ₁₋₄₀ and cholyl-A β ₆₋₂₀ were both present at 64 μ M. In panel B, A β ₁₋₄₀ was present at 30 μ M and cholyl-A β ₆₋₂₀ was present at 64 μ M. In panel C, A β ₁₋₄₀ was present at 10 μ M and cholyl-A β ₆₋₂₀ was present at 64 μ M. These data show that an equimolar amount of cholyl-A β ₆₋₂₀ is effective at inhibiting aggregation of A β ₁₋₄₀ (see Figure 4, panel A) and that as the concentration of A β ₁₋₄₀ is reduced, the amount of detectable aggregation of the A β ₁₋₄₀ monomer is correspondingly reduced (compare Figure 4, panels B and C with panel A). The corresponding results of the neurotoxicity analysis are shown in Figure 4, panels D, E, and F. These results demonstrate that the β -amyloid modulator compound not only inhibits aggregation of A β ₁₋₄₀ monomers but also inhibits the neurotoxicity of the A β ₁₋₄₀ solution, illustrated by the reduced percent toxicity of the cells when incubated with the A β ₁₋₄₀/modulator solution as compared to A β ₁₋₄₀ alone (see *e.g.*, Figure 4, panel D). Moreover, even when A β ₁₋₄₀ aggregation was not detectable as measured by light scattering, the modulator compound inhibited the neurotoxicity of the A β ₁₋₄₀ solution (see Figure 4, panels E and F). Thus, the formation of neurotoxic A β ₁₋₄₀ aggregates precedes the formation of insoluble aggregates detectable by light scattering and the modulator compound is effective at inhibiting the formation and/or activity of these neurotoxic aggregates. Similar results were seen with other modulator compounds, such as iminobiotinyl-A β ₆₋₂₀ (PPI-267), cholyl-A β ₁₆₋₂₀ (PPI-350) and cholyl-A β ₁₆₋₂₀-amide (PPI-319).

Additionally, the β -amyloid modulator compounds have been demonstrated to reduce the neurotoxicity of preformed A β ₁₋₄₀ aggregates. In these experiments, A β ₁₋₄₀ aggregates were preformed by incubation of the monomers in the absence of any modulators. The modulator compound was then incubated with the preformed A β ₁₋₄₀ aggregates for 24 hours at 37 °C, after which time the β -AP/modulator solution was collected and its neurotoxicity evaluated as described above. Incubation of preformed A β ₁₋₄₀ aggregates with the modulator compound prior to applying the solution to neuronal cells resulted in a decrease in the neurotoxicity of the A β ₁₋₄₀ solution. These results suggest that the modulator can either bind to A β fibrils or soluble aggregate and modulate their inherent neurotoxicity or that the modulator can perturb the equilibrium between monomeric and aggregated forms of A β ₁₋₄₀ in favor of the non-neurotoxic form.

EXAMPLE 11: Characterization of Additional β -Amyloid Modulator Compounds

In this example, additional modulator compounds designed based upon amino acids 17-20 of A β , LVFF (identified in Example 9), were prepared and analyzed to further delineate the structural features necessary for inhibition of β -amyloid aggregation. Types of compounds analyzed included ones having only three amino acid residues of an A β

aggregation-core domain, compounds in which the amino acid residues of an A β aggregation core domain were rearranged or in which amino acid substitutions had been made, compounds modified with a carboxy-terminal modifying group and compounds in which the modifying group had been derivatized. Abbreviations used in this example are: h- (free amino terminus), -oh (free carboxylic acid terminus), -nh₂ (amide terminus), CA (cholyl, the acyl portion of cholic acid), NANA (*N*-acetyl neuraminy), IB (iminobiotinyl), β A (β -alanyl), DA (D-alanyl), Adp (aminoethyldibenzofuranylpropanoic acid), Aic (3-(*O*-aminoethyl-*iso*)-cholyl, a derivative of cholic acid), IY (iodotyrosyl), o-methyl (carboxy-terminal methyl ester), *N*-me (*N*-methyl peptide bond), DeoxyCA (deoxycholyl) and LithoCA (lithocholyl).

Modulator compounds having an Aic modifying group at either the amino- or carboxy-terminus (e.g., PPI-408 and PPI-418) were synthesized using known methods (see e.g., Wess, G. *et al.* (1993) *Tetrahedron Letters*, 34:817-822; Wess, G. *et al.* (1992) *Tetrahedron Letters* 33:195-198). Briefly, 3-*iso-O*-(2-aminoethyl)-cholic acid (3 β -(2-aminoethoxy)-7 α ,12 α -dihydroxy-5 β -cholanoic acid) was converted to the Fmoc-protected derivative using Fmoc-OSu (the hydroxysuccinimide ester of the Fmoc group, which is commercially available) to obtain a reagent that was used to introduce the cholic acid derivative into the compound. For N-terminal introduction of the cholic acid moiety, the Fmoc-protected reagent was coupled to the N-terminal amino acid of a solid-phase peptide in the standard manner, followed by standard Fmoc-deprotection conditions and subsequent cleavage from the resin, followed by HPLC purification. For C-terminal introduction of the cholic acid moiety, the Fmoc-protected reagent was attached to 2-chlorotrityl chloride resin in the standard manner. This amino acyl derivatized resin was then used in the standard manner to synthesize the complete modified peptide.

The modulators were evaluated in the nucleation and seeded extension assays described in Example 6 and the results are summarized below in Table V. The change in lag time (Δ Lag) is presented as the ratio of the lag time observed in the presence of the test compound to the lag time of the control. Data are reported for assays in the presence of 100 mole % inhibitor relative to the concentration of A β ₁₋₄₀, except for PPI-315, PPI-348, PPI-380, PPI-407 and PPI-418, for which the data is reported in the presence of 33 mole % inhibitor. Inhibition (% I_{nuc'l'n}) is listed as the percent reduction in the maximum observed turbidity in the control at the end of the assay time period. Inhibition in the extension assay (% I_{ext'n}) is listed as the percent reduction of thioflavin-T fluorescence of β -structure in the presence of 25 mole % inhibitor. Compounds with a % I_{nuc'l'n} of at least 30% are highlighted in bold.

Table V

5

Certain compounds shown in Table V (PPI-319, PPI-349, PPI-350, PPI-368 and PPI-426) also were tested in neurotoxicity assays such as those described in Example 10. For each compound, the delay of the appearance of neurotoxicity relative to control coincided with the delay in the time at which polymerization of A β began in the nucleation assays.

10 This correlation between the prevention of formation of neurotoxic A β species and the prevention of polymerization of A β was consistently observed for all compounds tested.

The results shown in Table V demonstrate that at an effective modulator compound can comprise as few as three A β amino acids residues (see PPI-394, comprising the amino acid sequence VFF, which corresponds to A β ₁₈₋₂₀, and PPI-395, comprising the amino acid sequence FFA, which corresponds to A β ₁₉₋₂₁). The results also demonstrate that a modulator compound having a modulating group at its carboxy-terminus is effective at inhibiting A β aggregation (see PPI-408, modified at its C-terminus with Aic). Still further, the results demonstrate that the cholyl group, as a modulating group, can be manipulated while maintaining the inhibitory activity of the compounds (see PPI-408 and PPI-418, both of which comprise the cholyl derivative Aic). The free amino group of the Aic derivative of cholic acid represents a position at which a chelation group for ^{99m}Tc can be introduced, *e.g.*, to create a diagnostic agent. Additionally, the ability to substitute iodotyrosyl for phenylalanine at position 19 or 20 of the A β sequence (see PPI-396 and PPI-397) while maintaining the ability of the compound to inhibit A β aggregation indicates that the compound could be labeled with radioactive iodine, *e.g.*, to create a diagnostic agent, without loss of the inhibitory activity of the compound.

Finally, compounds with inhibitory activity were created using A β derived amino acids but wherein the amino acid sequence was rearranged or had a substitution with a non-A β -derived amino acid. Examples of such compounds include PPI-426, in which the sequence of A β ₁₇₋₂₁ (LVFFA) has been rearranged (FFVLA), PPI-372, in which the

30

74

sequence of A β ₁₆₋₂₀ (KLVFF) has been rearranged (FKFVL), and PPI-388, -389 and -390, in which the sequence of A β ₁₇₋₂₁ (LVFFA) has been substituted at position 17, 18 or 19, respectively, with an alanine residue (AVFFA for PPI-388, LAFFA for PPI-389 and LVAFA for PPI-390). The inhibitory activity of these compounds indicate that the presence in the compound of an amino acid sequence directly corresponding to a portion of A β is not essential for inhibitory activity, but rather suggests that maintenance of the hydrophobic nature of this core region, by inclusion of amino acid residues such as phenylalanine, valine, leucine, regardless of their precise order, can be sufficient for inhibition of A β aggregation.

10 **EXAMPLE 12: Characterization of β -Amyloid Modulator Compounds** **Comprising an Unmodified β -Amyloid Peptide**

To examine the ability of unmodified A β peptides to modulate aggregation of natural β -AP, a series of A β peptides having amino- and/or carboxy terminal deletions as compared to A β ₁₋₄₀, or having internal amino acids deleted (*i.e.*, noncontiguous peptides), were prepared. One peptide (PPI-220) had additional, non-A β -derived amino acid residues at its amino-terminus. These peptides all had a free amino group at the amino-terminus and a free carboxylic acid at the carboxy-terminus. These unmodified peptides were evaluated in assays as described in Example 7. The results are summarized below in Table VI, wherein the data is presented as described in Example 7. Compounds exhibiting at least a 1.5 fold increase in lag time are highlighted in bold.

Table VI

Reference #	A β Peptide	Mole %	Fold Increase in Lag Time	% Inhibition of Plateau
PPI-226	A β ₆₋₂₀	100	1.66	76
PPI-227	A β ₁₁₋₂₅	100	~1	47
PPI-228	A β ₁₆₋₃₀	100	>4.5	100
PPI-229	A β ₂₁₋₃₅	100	~1	~0
PPI-230	A β ₂₆₋₄₀	100	0.8	~0
PPI-231	A β ₁₋₁₅	100	~1	18
PPI-247	A β _{1-30, 36-40} (Δ 31-35)	100	~1	~0
PPI-248	A β _{1-25, 31-40} (Δ 26-30)	100	1.58	~0
PPI-249	A β _{1-20, 26-40} (Δ 21-25)	100	2.37	~0
PPI-250	A β _{1-15, 21-40} (Δ 16-20)	100	1.55	~0
PPI-251	A β _{1-10, 16-40} (Δ 11-15)	100	~1.2	~0
PPI-252	A β _{1-5, 11-40} (Δ 6-10)	100	1.9	33
PPI-253	A β ₆₋₄₀	100	1.9	~0
PPI-220	EEVVHHHHQQ-A β ₁₆₋₄₀	100	>4	100

75

The results shown in Table VI demonstrate that limited portions of the A β sequence can have a significant inhibitory effect on natural β -AP aggregation even when the peptide is not modified by a modifying group. Preferred unmodified peptides are A β ₆₋₂₀ (PPI-226), A β ₁₆₋₃₀ (PPI-228), A β _{1-20, 26-40} (PPI-249) and EEVVHHHHQQ-A β ₁₆₋₄₀ (PPI-220), the amino acid sequences of which are shown in SEQ ID NOs: 4, 14, 15, and 16, respectively.

Forming part of this disclosure is the appended Sequence Listing, the contents of which are summarize in the Table below.

SEQ ID NO:	Amino Acids	Peptide Sequence
1	43 amino acids	A β ₁₋₄₃
2	103 amino acids	APP C-terminus
3	43 amino acids	A β ₁₋₄₃ (19, 20 mutated)
4	HDSGYEVHHQKLVFF	A β ₆₋₂₀
5	HQKLVFFA	A β ₁₄₋₂₁
6	HQKLVFF	A β ₁₄₋₂₀
7	QKLVFFA	A β ₁₅₋₂₁
8	QKLVFF	A β ₁₅₋₂₀
9	KLVFFA	A β ₁₆₋₂₁
10	KLVFF	A β ₁₆₋₂₀
11	LVFFA	A β ₁₇₋₂₁
12	LVFF	A β ₁₇₋₂₀
13	LAFFA	A β ₁₇₋₂₁ (V ₁₈ →A)
14	KLVFFAEDVGSNKG	A β ₁₆₋₃₀
15	35 amino acids	A β _{1-20, 26-40}
16	35 amino acids	EEVVHHHHQQ- β AP ₁₆₋₄₀
17	AGAAAAGA	PrP peptide
18	AILSS	amylin peptide
19	VFF	A β ₁₈₋₂₀
20	FFA	A β ₁₉₋₂₁
21	FFVLA	A β ₁₇₋₂₁ (scrambled)
22	LVFFK	A β ₁₇₋₂₁ (A ₂₁ →K)
23	LV(IY)FA	A β ₁₇₋₂₁ (F ₁₉ →IY)
24	VFFA	A β ₁₈₋₂₁
25	AVFFA	A β ₁₇₋₂₁ (L ₁₇ →A)
26	LVF(IY)A	A β ₁₇₋₂₁ (F ₂₀ →IY)

§
CLAIMS

1. An amyloid modulator compound comprising an amyloidogenic protein, or peptide fragment thereof, coupled directly or indirectly to at least one modifying group such that the compound modulates the aggregation of natural amyloid proteins or peptides when contacted with the natural amyloidogenic proteins or peptides.

2. The compound of claim 1, which inhibits aggregation of natural amyloidogenic proteins or peptides when contacted with the natural amyloidogenic proteins or peptides.

3. The compound of claim 1, wherein the amyloidogenic protein, or peptide fragment thereof, is selected from the group consisting of transthyretin (TTR), prion protein (PrP), islet amyloid polypeptide (IAPP), atrial natriuretic factor (ANF), kappa light chain, lambda light chain, amyloid A, procalcitonin, cystatin C, β 2 microglobulin, ApoA-I, gelsolin, procalcitonin, calcitonin, fibrinogen and lysozyme.

4. A β -amyloid peptide compound comprising a formula:

wherein Xaa is a β -amyloid peptide having an amino-terminal amino acid residue corresponding to position 668 of β -amyloid precursor protein-770 (APP-770) or to a residue carboxy-terminal to position 668 of APP-770. A is a modifying group attached directly or indirectly to the β -amyloid peptide of the compound such that the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides, and n is an integer selected such that the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

5. The compound of claim 4, wherein at least one A group is attached directly or indirectly to the amino terminus of the β -amyloid peptide of the compound.

6. The compound of claim 4, wherein at least one A group is attached directly or indirectly to the carboxy terminus of the β -amyloid peptide of the compound.

7. The compound of claim 4, wherein at least one A group is attached directly or indirectly to a side chain of at least one amino acid residue of the β -amyloid peptide of the compound.

8. A β -amyloid modulator compound comprising an A β aggregation core domain (ACD) coupled directly or indirectly to at least one modifying group (MG) such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

9. The compound of claim 8, wherein the A β aggregation core domain is modeled after a subregion of natural β -amyloid peptide between 3 and 10 amino acids in length.

10. A β -amyloid modulator compound comprising a formula:

wherein Xaa₁, Xaa₂ and Xaa₃ are each amino acid structures and at least two of Xaa₁, Xaa₂ and Xaa₃ are, independently, selected from the group consisting of a leucine structure, a phenylalanine structure and a valine structure;

Y, which may or may not be present, is a peptidic structure having the formula (Xaa)_a, wherein Xaa is any amino acid structure and a is an integer from 1 to 15;

Z, which may or may not be present, is a peptidic structure having the formula (Xaa)_b, wherein Xaa is any amino acid structure and b is an integer from 1 to 15; and

A is a modifying group attached directly or indirectly to the compound and n is an integer;

Xaa₁, Xaa₂, Xaa₃, Y, Z, A and n being selected such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

11. The compound of claim 10, wherein Xaa₁ and Xaa₂ are each phenylalanine structures.

12. The compound of claim 10, wherein Xaa₂ and Xaa₃ are each phenylalanine structures.

13. A β -amyloid modulator compound comprising a formula:

wherein Xaa₁ and Xaa₃ are amino acid structures;

Xaa₂ is a valine structure;

Xaa₄ is a phenylalanine structure;

5 Y, which may or may not be present, is a peptidic structure having the formula (Xaa)_a, wherein Xaa is any amino acid structure and a is an integer from 1 to 15;

Z, which may or may not be present, is a peptidic structure having the formula (Xaa)_b, wherein Xaa is any amino acid structure and b is an integer from 1 to 15; and

10 A is a modifying group attached directly or indirectly to the compound and n is an integer;

Xaa₁, Xaa₃, Y, Z, A and n being selected such that the compound modulates the aggregation or inhibits the neurotoxicity of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

15 14. The compound of claim 13, wherein Xaa₁ is a leucine structure and Xaa₃ is phenylalanine structure.

15. A compound comprising the formula:

20 A-Xaa₁-Xaa₂-Xaa₃-Xaa₄-Xaa₅-Xaa₆-Xaa₇-Xaa₈-B

wherein Xaa₁ is a histidine structure;

Xaa₂ is a glutamine structure;

Xaa₃ is a lysine structure;

25 Xaa₄ is a leucine structure;

Xaa₅ is a valine structure;

Xaa₆ is a phenylalanine structure;

Xaa₇ is a phenylalanine structure;

Xaa₈ is an alanine structure;

30 A and B are modifying groups attached directly or indirectly to the amino terminus and carboxy terminus, respectively, of the compound;

and wherein Xaa₁-Xaa₂-Xaa₃, Xaa₁-Xaa₂ or Xaa₁ may or may not be present;

Xaa₈ may or may not be present; and

at least one of A and B is present.

35 16. A β -amyloid modulator compound comprising a modifying group attached directly or indirectly to a peptidic structure, wherein the peptidic structure comprises amino acid structures having an amino acid sequence selected from the group consisting of His-Gln-Lys-Leu-Val-Phe-Phe-Ala (SEQ ID NO: 5), His-Gln-Lys-Leu-Val-Phe-Phe (SEQ ID NO: 6),

Gln-Lys-Leu-Val-Phe-Phe-Ala (SEQ ID NO: 7), Gln-Lys-Leu-Val-Phe-Phe (SEQ ID NO: 8), Lys-Leu-Val-Phe-Phe-Ala (SEQ ID NO: 9), Lys-Leu-Val-Phe-Phe (SEQ ID NO: 10), Leu-Val-Phe-Phe-Ala (SEQ ID NO: 11), Leu-Val-Phe-Phe (SEQ ID NO: 12), Leu-Ala-Phe-Phe-Ala (SEQ ID NO: 13), Val-Phe-Phe (SEQ ID NO: 19), Phe-Phe-Ala (SEQ ID NO: 20), Phe-Phe-Val-Leu-Ala (SEQ ID NO: 21), Leu-Val-Phe-Phe-Lys (SEQ ID NO: 22), Leu-Val-Iodotyrosine-Phe-Ala (SEQ ID NO: 23), Val-Phe-Phe-Ala (SEQ ID NO: 24), Ala-Val-Phe-Phe-Ala (SEQ ID NO: 25), Leu-Val-Phe-Iodotyrosine-Ala (SEQ ID NO: 26), Leu-Val-Phe-Phe-Ala-Glu (SEQ ID NO: 27), Phe-Phe-Val-Leu (SEQ ID NO: 28), Phe-Lys-Phe-Val-Leu (SEQ ID NO: 29), Lys-Leu-Val-Ala-Phe (SEQ ID NO: 30), Lys-Leu-Val-Phe-Phe- β Ala (SEQ ID NO: 31) and Leu-Val-Phe-Phe-DAla (SEQ ID NO: 32).

17. The compound of claim 1-16, wherein the modifying group comprises a cyclic, heterocyclic or polycyclic group.

18. The compound of claim 1-16, wherein the modifying group contains a cis-decalin group.

19. The compound of claim 1-16, wherein the modifying group contains a cholanyl structure.

20. The compound of claim 1-16, wherein the modifying group is a cholyl group.

21. The compound of claim 1-16, wherein the modifying group comprises a biotin-containing group, a diethylene-triaminepentaacetyl group, a (-)-menthoxyacetyl group, a fluorescein-containing group or an N-acetylneuraminyl group.

22. The compound of claim 1-16, which is further modified to alter a pharmacokinetic property of the compound.

23. The compound of claim 1-16, which is further modified to label the compound with a detectable substance.

24. The β -amyloid modulator which inhibits aggregation of natural β -amyloid peptides when contacted with a molar excess amount of natural β -amyloid peptides.

25. A β -amyloid peptide compound comprising an amino acid sequence having at least one amino acid deletion compared to β AP₁₋₃₉, such that the compound inhibits aggregation of natural β -amyloid peptides when contacted with the natural β -amyloid peptides.

26. The compound of claim 25, comprising an amino acid sequence which has at least one internal amino acid deleted compared to β AP₁₋₃₉.

5

27. The compound of claim 25, comprising an amino acid sequence which has at least one N-terminal amino acid deleted compared to β AP₁₋₃₉.

10

28. The compound of claim 25, comprising an amino acid sequence which has at least one C-terminal amino acid deleted compared to β AP₁₋₃₉.

29. A compound selected from the group consisting of β AP₆₋₂₀ (SEQ ID NO: 4), β AP₁₆₋₃₀ (SEQ ID NO: 14), β AP_{1-20, 26-40} (SEQ ID NO: 15) and EEVVHHHHQQ- β AP₁₆₋₄₀ (SEQ ID NO: 16).

15

30. A pharmaceutical composition comprising the compound of claim 1-29 and a pharmaceutically acceptable carrier.

20

31. Use of the compound of claim 1-29 in the manufacture of a medicament for the diagnosis of an amyloidogenic disease.

32. Use of the compound of claim 1-29 in the manufacture of a medicament for the treatment of an amyloidogenic disease.

25

33. A method for inhibiting aggregation of natural β -amyloid peptides, comprising contacting the natural β -amyloid peptides with the compound of claims 4-29 such that aggregation of the natural β -amyloid peptides is inhibited.

30

34. A method for inhibiting neurotoxicity of natural β -amyloid peptides, comprising contacting the natural β -amyloid peptides with the compound of claim 4-29 such that neurotoxicity of the natural β -amyloid peptides is inhibited.

35. A method for detecting the presence or absence of natural β -amyloid peptides in a biological sample, comprising:

35

contacting a biological sample with the compound of 4-29; and

detecting the compound bound to natural β -amyloid peptides to thereby detect the presence or absence of natural β -amyloid peptides in the biological sample.

36. - The method of claim 35, wherein the β -amyloid modulator compound and the biological sample are contacted *in vitro*.

37. The method of claim 35, wherein the β -amyloid modulator compound is
5 contacted with the biological sample by administering the β -amyloid modulator compound to a subject.

38. The method of claim 37, wherein the compound is labeled with radioactive
10 technetium or radioactive iodine.

39. A method for detecting natural β -amyloid peptides to facilitate diagnosis of a
 β -amyloidogenic disease, comprising:
contacting a biological sample with the compound of claim 4-29; and
15 detecting the compound bound to natural β -amyloid peptides to facilitate diagnosis of a β -amyloidogenic disease.

40. The method of claim 39, wherein the β -amyloid modulator compound and the biological sample are contacted *in vitro*.

20 41. The method of claim 39, wherein the β -amyloid modulator compound is contacted with the biological sample by administering the β -amyloid modulator compound to a subject.

25 42. The method of claim 41, wherein the compound is labeled with radioactive technetium or radioactive iodine.

43. The method of claim 39, which facilitates diagnosis of Alzheimer's disease.

30 44. A method for treating a subject for a disorder associated with amyloidosis, comprising:
administering to the subject a therapeutically or prophylactically effective amount of the compound of claim 1-3 such that the subject is treated for a disorder associated with amyloidosis.

35 45. The method of claim 44, wherein the disorder is selected from the group consisting of familial amyloid polyneuropathy (Portuguese, Japanese and Swedish types), familial amyloid cardiomyopathy (Danish type), isolated cardiac amyloid, systemic senile amyloidosis, scrapie, bovine spongiform encephalopathy, Creutzfeldt-Jakob disease, Gerstmann-Straussler-Scheinker syndrome, adult onset diabetes, insulinoma, isolated atrial

94

amyloidosis, idiopathic (primary) amyloidosis, myeloma or macroglobulinemia-associated amyloidosis, primary localized cutaneous nodular amyloidosis associated with Sjogren's syndrome, reactive (secondary) amyloidosis, familial Mediterranean Fever and familial amyloid nephropathy with urticaria and deafness (Muckle-Wells syndrome), hereditary cerebral hemorrhage with amyloidosis of Icelandic type, amyloidosis associated with long term hemodialysis, hereditary non-neuropathic systemic amyloidosis (familial amyloid polyneuropathy III), familial amyloidosis of Finnish type, amyloidosis associated with medullary carcinoma of the thyroid, fibrinogen-associated hereditary renal amyloidosis and lysozyme-associated hereditary systemic amyloidosis.

46. A method for treating a subject for a disorder associated with β -amyloidosis, comprising:

administering to the subject a therapeutically effective amount of the compound of claim 4-29 such that the subject is treated for a disorder associated with β -amyloidosis.

47. The method of claim 46, wherein the disorder is Alzheimer's disease.

48. A method for treating a subject for a disorder associated with β -amyloidosis, comprising:

administering to the subject a recombinant expression vector encoding the compound of claim 25-29 such that the compound is synthesized in the subject and the subject is treated for a disorder associated with β -amyloidosis.

49. The method of claim 48, wherein the disorder is Alzheimer's disease.

INTERNATIONAL SEARCH REPORT

Intern: ial application No.

PCT/US 96/ 03492

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
See Further Information sheet enclosed.
- see "Remark" -
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such
an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all
searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment
of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report
covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is
restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International Application No. PCT/US96/ 03492

FURTHER INFORMATION CONTINUED FROM PCT/ISA/210

Remark : Although claims 33-35, 37-39 and 41-49 as far as related to in vivo methods are directed to a method of treatment of (diagnostic method practised on) the human/animal body the search has been carried out and based on the alleged effects of the compound/composition.

OBSCURITIES

The scope of the claims 1-13 and 17-21 is very broad and speculative. Compounds which are mainly, and in at least part of the claims even exclusively, defined by expressions like "amyloidogenic protein" and "modifying group", which expressions themselves are ill-defined, cannot be considered to represent a clear and concise definition of patentable subject matter (Art.6 PCT)

Furthermore the available experimental data actually only comprise a very small part of the compounds claimed, which part is moreover not evenly distributed over the whole claimed area (actually only specifically modified fragments of beta-amyloid protein have been exemplified). Therefore the claims can also not be considered to represent a permissible generalization which is fairly based on experimental evidence, that is, they are also not adequately supported by the description (Art.6 PCT)

Therefore a meaningful and economically feasible search could not encompass the complete subject-matter of the claims.

Consequently the search has been limited to the actually synthesized examples and (closely) related analogs and therefore only the claims 14-16 and 25-29 have been searched completely. (Art.17(2)(a)(ii)PCT)

Claims searched completely : 14-16, 25-29.

Claims searched incompletely : 1, 2, 4-13, 17-24, 30-49

Claims not searched : 3
